Package ‘CoxBoost’

February 19, 2015

Version 1.4
Title Cox models by likelihood based boosting for a single survival endpoint or competing risks
Author Harald Binder <binderh@uni-mainz.de>
Maintainer Harald Binder <binderh@uni-mainz.de>
Depends R (>= 2.14.0), survival, Matrix, prodlim
Suggests parallel, snowfall
Description This package provides routines for fitting Cox models by likelihood based boosting for a single endpoint or in presence of competing risks

 coef.CoxBoost  

**Coefficients from CoxBoost fit**

**Description**

Extracts the coefficients from the specified boosting steps of a CoxBoost object fitted by `CoxBoost`.

**Usage**

```r
## S3 method for class 'CoxBoost'
coef(object, at.step=NULL, scaled=TRUE, ...)
```

**Arguments**

- `object`: fitted CoxBoost object from a `CoxBoost` call.
- `at.step`: scalar or vector of boosting step(s) at which prediction is wanted. If no step is given, the final boosting step is used.
- `scaled`: logical value indicating whether coefficients should be returned scaled to be at the level of the original covariate values, or unscaled as used internally when `standardize=TRUE` is used in the `CoxBoost` call.
- `...`: miscellaneous arguments, none of which is used at the moment.

**Value**

For a vector of length `p` (number of covariates) (`at.step` being a scalar) or a length(`at.step`) * `p` matrix (`at.step` being a vector).

**Author(s)**

Harald Binder `<binderh@uni-mainz.de>`

CoxBoost  

**Fit a Cox model by likelihood based boosting**

**Description**

CoxBoost is used to fit a Cox proportional hazards model by componentwise likelihood based boosting. It is especially suited for models with a large number of predictors and allows for mandatory covariates with unpenalized parameter estimates.

**Usage**

```r
CoxBoost(time, status, x, unpen.index=NULL, standardize=TRUE, subset=1:length(time),
  weights=NULL, stepno=100, penalty=9*sum(status[subset]==1),
  criterion = c("pscore", "score", "hpscore", "hscore"),
  steps.size.factor=1, sf.scheme=c("sigmoid","linear"), pendistmat=NULL,
  connected.index=NULL, x.is.01=FALSE, return.score=TRUE, trace=FALSE)
```
**Arguments**

- **time**: vector of length \( n \) specifying the observed times.
- **status**: censoring indicator, i.e., vector of length \( n \) with entries 0 for censored observations and 1 for uncensored observations. If this vector contains elements not equal to 0 or 1, these are taken to indicate events from a competing risk and a model for the subdistribution hazard with respect to event 1 is fitted (see e.g. Fine and Gray, 1999; Binder et al. 2009a).
- **x**: \( n \times p \) matrix of covariates.
- **unpen.index**: vector of length \( p \).unpen with indices of mandatory covariates, where parameter estimation should be performed unpenalized.
- **standardize**: logical value indicating whether covariates should be standardized for estimation. This does not apply for mandatory covariates, i.e., these are not standardized.
- **subset**: a vector specifying a subset of observations to be used in the fitting process.
- **weights**: optional vector of length \( n \), for specifying weights for the individual observations.
- **penalty**: penalty value for the update of an individual element of the parameter vector in each boosting step.
- **criterion**: indicates the criterion to be used for selection in each boosting step. "pscore" corresponds to the penalized score statistics, "score" to the un-penalized score statistics. Different results will only be seen for un-standardized covariates ("pscore" will result in preferential selection of covariates with larger covariance), or if different penalties are used for different covariates. "hpscore" and "hscor" correspond to "pscore" and "score". However, a heuristic is used for evaluating only a subset of covariates in each boosting step, as described in Binder et al. (2011). This can considerably speed up computation, but may lead to different results.
- **stepsize.factor**: determines the step-size modification factor by which the natural step size of boosting steps should be changed after a covariate has been selected in a boosting step. The default (value 1) implies constant penalties, for a value < 1 the penalty for a covariate is increased after it has been selected in a boosting step, and for a value > 1 the penalty it is decreased. If pendistmat is given, penalty updates are only performed for covariates that have at least one connection to another covariate.
- **sf.scheme**: scheme for changing step sizes (via stepsize.factor). "linear" corresponds to the scheme described in Binder and Schumacher (2009b), "sigmoid" employs a sigmoid shape.
- **pendistmat**: connection matrix with entries ranging between 0 and 1, with entry \((i, j)\) indicating the certainty of the connection between covariates \(i\) and \(j\). According to this information penalty changes due to stepsize.factor < 1 are propagated, i.e., if entry \((i, j)\) is non-zero, the penalty for covariate \(j\) is decreased after it has been increased for covariate \(i\), after it has been selected in a boosting step. This matrix either has to have dimension \((p - p.unpen) \times (p - p.unpen)\) or the indicies of the p.connected connected covariates have to be given in
CoxBoost

in which case the matrix has to have dimension \( p_{\text{connected}} \times p_{\text{connected}} \). Generally, sparse matrices from package Matrix can be used to save memory.

indices of the \( p_{\text{connected}} \) connected covariates, for which `pendistmat` provides the connection information for distributing changes in penalties. No overlap with `unpen.index` is allowed. If `NULL`, and a connection matrix is given, all covariates are assumed to be connected.

number of boosting steps (\( m \)).

logical value indicating whether (the non-mandatory part of) \( x \) contains just values 0 and 1, i.e., binary covariates. If this is the case and indicated by this argument, computations are much faster.

logical value indicating whether the value of the score statistic (or penalized score statistic, depending on `criterion`), as evaluated in each boosting step for every covariate, should be returned. The corresponding element `scoremat` can become very large (and needs much memory) when the number of covariates and boosting steps is large.

logical value indicating whether progress in estimation should be indicated by printing the name of the covariate updated.

In contrast to gradient boosting (implemented e.g. in the `glmboost` routine in the R package mboost, using the CoxPH loss function), CoxBoost is not based on gradients of loss functions, but adapts the offset-based boosting approach from Tutz and Binder (2007) for estimating Cox proportional hazards models. In each boosting step the previous boosting steps are incorporated as an offset in penalized partial likelihood estimation, which is employed for obtain an update for one single parameter, i.e., one covariate, in every boosting step. This results in sparse fits similar to Lasso-like approaches, with many estimated coefficients being zero. The main model complexity parameter, which has to be selected (e.g. by cross-validation using `cv.coxboost`), is the number of boosting steps `stepno`. The penalty parameter `penalty` can be chosen rather coarsely, either by hand or using `optimCoxBoostPenalty`.

The advantage of the offset-based approach compared to gradient boosting is that the penalty structure is very flexible. In the present implementation this is used for allowing for unpenalized mandatory covariates, which receive a very fast coefficient build-up in the course of the boosting steps, while the other (optional) covariates are subjected to penalization. For example in a microarray setting, the (many) microarray features would be taken to be optional covariates, and the (few) potential clinical covariates would be taken to be mandatory, by including their indices in `unpen.index`.

If a group of correlated covariates has influence on the response, e.g. genes from the same pathway, componentwise boosting will often result in a non-zero estimate for only one member of this group. To avoid this, information on the connection between covariates can be provided in `pendistmat`. If then, in addition, a penalty updating scheme with `stepsizes.factor < 1` is chosen, connected covariates are more likely to be chosen in future boosting steps, if a directly connected covariate has been chosen in an earlier boosting step (see Binder and Schumacher, 2009b).

Value

CoxBoost returns an object of class CoxBoost.

cv.CoxBoost

Determines the optimal number of boosting steps by cross-validation

Description

Performs a K-fold cross-validation for CoxBoost in search for the optimal number of boosting steps.

Usage

cv.CoxBoost(time,status,x,subset=1:length(time),maxstepno=100,K=10,
type=c("verweij","naive"),
parallel=FALSE/upload.x=TRUE, multicore=FALSE,
folds=NULL, trace=FALSE,...)
**Arguments**

- **time**: vector of length \( n \) specifying the observed times.
- **status**: censoring indicator, i.e., vector of length \( n \) with entries 0 for censored observations and 1 for uncensored observations. If this vector contains elements not equal to 0 or 1, these are taken to indicate events from a competing risk and a model for the subdistribution hazard with respect to event 1 is fitted (see e.g. Fine and Gray, 1999).
- **x**: \( n \times p \) matrix of covariates.
- **subset**: a vector specifying a subset of observations to be used in the fitting process.
- **maxstepno**: maximum number of boosting steps to evaluate, i.e., the returned “optimal” number of boosting steps will be in the range \([0, \text{maxstepno}]\).
- **K**: number of folds to be used for cross-validation. If \( K \) is larger or equal to the number of non-zero elements in **status**, leave-one-out cross-validation is performed.
- **type**: way of calculating the partial likelihood contribution of the observation in the hold-out folds: “verweij” uses the more appropriate method described in Verweij and van Houwelingen (1996), “naive” uses the approach where the observations that are not in the hold-out folds are ignored (often found in other R packages).
- **parallel**: logical value indicating whether computations in the cross-validation folds should be performed in parallel on a compute cluster, using package `snowfall`. Parallelization is performed via the package `snowfall` and the initialization function of this package, `sfInit`, should be called before calling `cv.CoxBoost`.
- **multicore**: indicates whether computations in the cross-validation folds should be performed in parallel, using package `parallel`. If TRUE, package `parallel` is employed using the default number of cores. A value larger than 1 is taken to be the number of cores that should be employed.
- **upload.x**: logical value indicating whether x should/has to be uploaded to the compute cluster for parallel computation. Uploading this only once (using `sfExport(x)` from library `snowfall`) can save much time for large data sets.
- **folds**: if not NULL, this has to be a list of length \( K \), each element being a vector of indices of fold elements. Useful for employing the same folds for repeated runs.
- **trace**: logical value indicating whether progress in estimation should be indicated by printing the number of the cross-validation fold and the index of the covariate updated.
- **...**: miscellaneous parameters for the calls to `CoxBoost`.

**Value**

List with the following components:

- **mean.logplik**: vector of length `maxstepno+1` with the mean partial log-likelihood for boosting steps 0 to `maxstepno`.
- **se.logplik**: vector with standard error estimates for the mean partial log-likelihood criterion for each boosting step.
optimal.step  optimal boosting step number, i.e., with minimum mean partial log-likelihood.
folds          list of length K, where the elements are vectors of the indices of observations in the respective folds.

summary(cbfit)

## End(Not run)
```
cvcb.control

Control parameters for cross-validation in iCoxBoost

Description

This function allows to set the control parameters for cross-validation to be passed into a call to iCoxBoost.

Usage

```r
cvcb.control(K=10,type=c("verweij","naive"),parallel=FALSE,
upload.x=TRUE,multicore=FALSE,folds=NULL)
```

Arguments

```r
K
```
number of folds to be used for cross-validation. If K is larger or equal to the number of events in the data to be analyzed, leave-one-out cross-validation is performed.

```r
type
```
way of calculating the partial likelihood contribution of the observation in the hold-out folds: "verweij" uses the more appropriate method described in Verweij and van Houwelingen (1996), "naive" uses the approach where the observations that are not in the hold-out folds are ignored (often found in other R packages).

```r
parallel
```
logical value indicating whether computations in the cross-validation folds should be performed in parallel on a compute cluster, using package snowfall. Parallelization is performed via the package snowfall and the initialization function of this package, sfInit, should be called before calling iCoxBoost.

```r
multicore
```
indicates whether computations in the cross-validation folds should be performed in parallel, using package parallel. If TRUE, package parallel is employed using the default number of cores. A value larger than 1 is taken to be the number of cores that should be employed.

```r
upload.x
```
logical value indicating whether x should/has to be uploaded to the compute cluster for parallel computation. Uploading this only once (using sfExport(x) from library snowfall) can save much time for large data sets.

```r
folds
```
if not NULL, this has to be a list of length K, each element being a vector of indices of fold elements. Useful for employing the same folds for repeated runs.

Value

List with elements corresponding to the call arguments.

iCoxBoost, cv.CoxBoost

estimPVal

Estimate p-values for a model fitted by CoxBoost

Description

Performs permutation-based p-value estimation for the optional covariates in a fit from CoxBoost.

Usage

estimPVal(object, x, permute.n = 10, per.covariate = FALSE, parallel = FALSE, multicore = FALSE, trace = FALSE, ...)

Arguments

object fit object obtained from CoxBoost.

x n * p matrix of covariates. This has to be the same that was used in the call to CoxBoost.

permute.n number of permutations employed for obtaining a null distribution.

ter.covariate logical value indicating whether a separate null distribution should be considered for each covariate. A larger number of permutations will be needed if this is wanted.

parallel logical value indicating whether computations for obtaining a null distribution via permutation should be performed in parallel on a compute cluster. Parallelization is performed via the package snowfall and the initialization function of this package, sfInit, should be called before calling estimPVal.

multicore indicates whether computations in the permuted data sets should be performed in parallel, using package parallel. If TRUE, package parallel is employed using the default number of cores. A value larger than 1 is taken to be the number of cores that should be employed.

trace logical value indicating whether progress in estimation should be indicated by printing the number of the permutation that is currently being evaluated.

... miscellaneous parameters for the calls to CoxBoost
Details

As p-value estimates are based on permutations, random numbers are drawn for determining permutation indices. Therefore, the results depend on the state of the random number generator. This can be used to explore the variability due to random variation and help to determine an adequate value for permute.n. A value of 100 should be sufficient, but this can be quite slow. If there is a considerable number of covariates, e.g., larger than 100, a much smaller number of permutations, e.g., 10, might already work well. The estimates might also be negatively affected, if only a small number of boosting steps (say <50) was employed for the original fit.

Value

Vector with p-value estimates, one value for each optional covariate specified in the original call to `coxboost`.

                   penalty=100)

# estimate p-values

p1 <- estimPVal(cbfit,x,permute.n=10)

# get a second vector of estimates for checking how large
# random variation is
```
iCoxBoost

Interface for cross-validation and model fitting using a formula description

Description
Formula interface for fitting a Cox proportional hazards model by componentwise likelihood based boosting (via a call to \texttt{coxboost}), where cross-validation can be performed automatically for determining the number of boosting steps (via a call to \texttt{cv.CoxBoost}).

Usage
\begin{verbatim}
iCoxBoost(formula, data=NULL, weights=NULL, subset=NULL, mandatory=NULL, cause=1, standardize=TRUE, stepno=200, criterion=c("pscore","score","hpscore","hscore"), nu=0.1, stepsize.factor=1, varlink=NULL, cv=cvcb.control(), trace=FALSE,...)
\end{verbatim}

Arguments

\begin{itemize}
\item \texttt{formula} A formula describing the model to be fitted, similar to a call to \texttt{coxph}. The response must be a survival object, either as returned by \texttt{Surv} or \texttt{Hist} (in a competing risks application).
\item \texttt{data} data frame containing the variables described in the formula.
\item \texttt{weights} optional vector, for specifying weights for the individual observations.
\item \texttt{subset} a vector specifying a subset of observations to be used in the fitting process.
\item \texttt{mandatory} vector containing the names of the covariates whose effect is to be estimated un-regularized.
\item \texttt{cause} cause of interest in a competing risks setting, when the response is specified by \texttt{Hist} (see e.g. Fine and Gray, 1999; Binder et al. 2009a).
\item \texttt{standardize} logical value indicating whether covariates should be standardized for estimation. This does not apply for mandatory covariates, i.e., these are not standardized.
\item \texttt{stepno} maximum number of boosting steps to be evaluated when determining the number of boosting steps by cross-validation, otherwise the number of boosting steps itself.
\end{itemize}
criterion indicates the criterion to be used for selection in each boosting step. "pscore" corresponds to the penalized score statistics, "score" to the un-penalized score statistics. Different results will only be seen for un-standardized covariates ("pscore" will result in preferential selection of covariates with larger covariance), or if different penalties are used for different covariates. "hpscore" and "hscore" correspond to "pscore" and "score". However, a heuristic is used for evaluating only a subset of covariates in each boosting step, as described in Binder et al. (2011). This can considerably speed up computation, but may lead to different results.

nu (roughly) the fraction of the partial maximum likelihood estimate used for the update in each boosting step. This is converted into a penalty for the call to CoxBoost. Use smaller values, e.g., 0.01 when there is little information in the data, and larger values, such as 0.1, with much information or when the number of events is larger than the number of covariates. Note that the default for direct calls to CoxBoost corresponds to nu=0.1.

stepsize.factor determines the step-size modification factor by which the natural step size of boosting steps should be changed after a covariate has been selected in a boosting step. The default (value 1) implies constant nu, for a value < 1 the value nu for a covariate is decreased after it has been selected in a boosting step, and for a value > 1 the value nu is increased. If pendistmat is given, updates of nu are only performed for covariates that have at least one connection to another covariate.

varlink list for specifying links between covariates, used to re-distribute step sizes when stepsize.factor != 1. The list needs to contain at least two vectors, the first containing the name of the source covariates, the second containing the names of the corresponding target covariates, and a third (optional) vector containing weights between 0 and 1 (defaulting to 1). If nu is increased/decreased for one of the source covariates according to stepsize.factor, the nu for the corresponding target covariate is decreased/increased accordingly (multiplied by the weight). If formula contains interaction terms, als rules for these can be set up, using variable names such as V1:V2 for the interaction term between covariates V1 and V2.

cv TRUE, for performing cross-validation, with default parameters, FALSE for not performing cross-validation, or list containing the parameters for cross-validation, as obtained from a call to cvb.control.

trace logical value indicating whether progress in estimation should be indicated by printing the name of the covariate updated.

Miscellaneous arguments, passed to the call to cv.CoxBoost.

Details

In contrast to gradient boosting (implemented e.g. in the glmboost routine in the R package mboost, using the CoxPH loss function), CoxBoost is not based on gradients of loss functions, but adapts the offset-based boosting approach from Tutz and Binder (2007) for estimating Cox proportional hazards models. In each boosting step the previous boosting steps are incorporated as an offset in penalized partial likelihood estimation, which is employed for obtain an update for one single parameter,
i.e., one covariate, in every boosting step. This results in sparse fits similar to Lasso-like approaches, with many estimated coefficients being zero. The main model complexity parameter, the number of boosting steps, is automatically selected by cross-validation using a call to `cv.CoxBoost`). Note that this will introduce random variation when repeatedly calling `icCoxBoost`, i.e. it is advised to set/save the random number generator state for reproducible results.

The advantage of the offset-based approach compared to gradient boosting is that the penalty structure is very flexible. In the present implementation this is used for allowing for unpenalized mandatory covariates, which receive a very fast coefficient build-up in the course of the boosting steps, while the other (optional) covariates are subjected to penalization. For example in a microarray setting, the (many) microarray features would be taken to be optional covariates, and the (few) potential clinical covariates would be taken to be mandatory, by including their names in `mandatory`.

If a group of correlated covariates has influence on the response, e.g. genes from the same pathway, componentwise boosting will often result in a non-zero estimate for only one member of this group. To avoid this, information on the connection between covariates can be provided in `varlink`. If then, in addition, a penalty updating scheme with `stepsize.factor < 1` is chosen, connected covariates are more likely to be chosen in future boosting steps, if a directly connected covariate has been chosen in an earlier boosting step (see Binder and Schumacher, 2009b).

Value

`icCoxBoost` returns an object of class `icCoxBoost`, which also has class `CoxBoost`. In addition to the elements from `CoxBoost` it has the following elements:

- `call`, `formula`, `terms`

  call, formula and terms from the formula interface.

- `cause`

  cause of interest.

- `cv.res`

  result from `cv.CoxBoost`, if cross-validation has been performed.

optimCoxBoostPenalty

Coarse line search for adequate penalty parameter

Description

This routine helps in finding a penalty value that leads to an “optimal” number of boosting steps for CoxBoost, determined by cross-validation, that is not too small/in a specified range.

Usage

optimCoxBoostPenalty(time, status, x, minstepno=50, maxstepno=200,
                       start.penalty=9*sum(status==1), iter.max=10,
                       upper.margin=0.05, parallel=FALSE,
                       trace=FALSE, ...)

Arguments

time vector of length n specifying the observed times.
optimCoxBoostPenalty

status
censoring indicator, i.e., vector of length n with entries 0 for censored observations and 1 for uncensored observations. If this vector contains elements not equal to 0 or 1, these are taken to indicate events from a competing risk and a model for the subdistribution hazard with respect to event 1 is fitted (see e.g. Fine and Gray, 1999).

x
n * p matrix of covariates.

minstepno, maxstepno
range of boosting steps in which the “optimal” number of boosting steps is wanted to be.

start.penalty
start value for the search for the appropriate penalty.

iter.max
maximum number of search iterations.

upper.margin
specifies the fraction of maxstepno which is used as an upper margin in which a cross-validation minimum is not taken to be one. This is necessary because of random fluctuations of cross-validated partial log-likelihood.

parallel
logical value indicating whether computations in the cross-validation folds should be performed in parallel on a compute cluster. Parallelization is performed via the package snowfall and the initialization function of of this package, sfInit, should be called before calling cv.CoxBoost.

trace
logical value indicating whether information on progress should be printed.

... miscellaneous parameters for cv.CoxBoost.

Details
The penalty parameter for CoxBoost has to be chosen only very coarsely. In Tutz and Binder (2006) it is suggested for likelihood based boosting just to make sure, that the optimal number of boosting steps, according to some criterion such as cross-validation, is larger or equal to 50. With a smaller number of steps, boosting may become too “greedy” and show sub-optimal performance. This procedure uses a very coarse line search and so one should specify a rather large range of boosting steps.

Value
List with element penalty containing the “optimal” penalty and cv.res containing the corresponding result of cv.CoxBoost.

**optimStepSizeFactor**  
*Coarse line search for optimum step-size modification factor*

**Description**

This routine helps in finding an optimum step-size modification factor for *CoxBoost*, i.e., that results in an optimum in terms of cross-validated partial log-likelihood.

**Usage**

```r
optimStepSizeFactor(time,status,x,
                     direction=c("down","up","both"),start.stepsize=0.1,
                     iter.max=10,constant.cv.res=NULL,
                     parallel=FALSE,trace=FALSE,...)
```

**Arguments**

- `time`: vector of length n specifying the observed times.
status censoring indicator, i.e., vector of length \( n \) with entries \( 0 \) for censored observations and \( 1 \) for uncensored observations. If this vector contains elements not equal to \( 0 \) or \( 1 \), these are taken to indicate events from a competing risk and a model for the subdistribution hazard with respect to event 1 is fitted (see e.g. Fine and Gray, 1999).

\( x \) \( n \times p \) matrix of covariates.

direction direction of line search for an optimal step-size modification factor (starting from value 1).

start.size step size used for the line search. A final step is performed using half this size.

iter.max maximum number of search iterations.

constant.cv.res result of \texttt{cv.CoxBoost} for \texttt{stepsize.factor}=1, that can be provided for saving computing time, if it already is available.

parallel logical value indicating whether computations in the cross-validation folds should be performed in parallel on a compute cluster. Parallelization is performed via the package \texttt{snowfall} and the initialization function of this package, \texttt{sfInit}, should be called before calling \texttt{cv.CoxBoost}.

trace logical value indicating whether information on progress should be printed.

... miscellaneous parameters for \texttt{cv.CoxBoost}.

Details

A coarse line search is performed for finding the best parameter \texttt{stepsize.factor} for \texttt{CoxBoost}. If an \texttt{pendistmat} argument is provided (which is passed on to \texttt{CoxBoost}), a search for factors smaller than 1 is sensible (corresponding to \texttt{direction="down"}). If no connection information is provided, it is reasonable to employ \texttt{direction="both"}, for avoiding restrictions without subject matter knowledge.

Value

List with the following components:

- \texttt{factor.list} array with the evaluated step-size modification factors.
- \texttt{critmat} matrix with the mean partial log-likelihood for each step-size modification factor in the course of the boosting steps.
- \texttt{optimal.factor.index} index of the optimal step-size modification factor.
- \texttt{optimal.factor} optimal step-size modification factor.
- \texttt{optimal.step} optimal boosting step number, i.e., with minimum mean partial log-likelihood, for step-size modification factor \texttt{optimal.factor}.

plot.CoxBoost

Plot coefficient paths from CoxBoost fit

Description

Plots coefficient paths, i.e. the parameter estimates plotted against the boosting steps as obtained from a CoxBoost object fitted by CoxBoost.
Usage

## S3 method for class 'CoxBoost'
plot(x, line.col = "dark grey", label.cex = 0.6, xlab = NULL, ylab = NULL, xlim = NULL, ylim = NULL,...)

Arguments

- **x**: fitted CoxBoost object from a CoxBoost call.
- **line.col**: color of the lines of the coefficient path.
- **label.cex**: scaling factor for the variable labels.
- **xlab**: label for the x axis, default label when NULL.
- **ylab**: label for the y axis, default label when NULL.
- **xlim, ylim**: plotting ranges, default label when NULL.
- **...**: miscellaneous arguments, passed to the plot routine.

Value

No value is returned, but a plot is generated.

**predict.CoxBoost**

*Predict method for CoxBoost fits*

Description

Obtains predictions at specified boosting steps from a CoxBoost object fitted by CoxBoost.

Usage

## S3 method for class 'CoxBoost'
predict(object, newdata = NULL, newtime = NULL, newstatus = NULL, subset = NULL, at.step = NULL, times = NULL, type = c("lp", "loglik", "risk", "CIF"),...)

Arguments

- **object**: fitted CoxBoost object from a CoxBoost call.
- **newdata**: \(n \times p\) matrix with new covariate values. If just prediction for the training data is wanted, it can be omitted.
predict.CoxBoost

newtime, newstatus
vectors with observed time and censoring indicator (0 for censoring, 1 for no
censoring, and any other values for competing events in a competing risks set-
ting) for new observations, where prediction is wanted. Only required if pre-
dicted partial log-likelihood is wanted, i.e., if type="logplik". This can also be
omitted when prediction is only wanted for the training data, i.e., newdata=NULL.

subset
an optional vector specifying a subset of observations to be used for evaluation.

at.step
scalar or vector of boosting step(s) at which prediction is wanted. If type="risk"
is used, only one step is admissible. If no step is given, the final boosting step is
used.

times
vector with T time points where prediction is wanted. Only needed for type="risk"

type
type of prediction to be returned: "lp" gives the linear predictor, "logplik" the
partial log-likelihood, "risk" the predicted probability of not yet having had
the event at the time points given in times, and "CIF" the predicted cumulative
incidence function, i.e., the predicted probability of having had the event of
interest.

... miscellaneous arguments, none of which is used at the moment.

Value
For type="lp" and type="logplik" a vector of length n.new (at.step being a scalar) or a
n.new * length(at.step) matrix (at.step being a vector) with predictions is returned. For
type="risk" or type="CIF" a n.new * T matrix with predicted probabilities at the specific time
points is returned.

Examples

```r
# Generate some survival data with 10 informative covariates
n <- 200; p <- 100
beta <- c(rep(1,10),rep(0,p-10))
x <- matrix(rnorm(n*p),n,p)
real.time <- -(log(runif(n)))/(10*exp(x %*% beta))
cens.time <- rexp(n(rate=1/10)
status <- ifelse(real.time <= cens.time,1,0)
obs.time <- ifelse(real.time <= cens.time,real.time,cens.time)

# define training and test set
train.index <- 1:100
test.index <- 101:200

# Fit CoxBoost to the training data
cbfit <- CoxBoost(time=obs.time[train.index],status=status[train.index],
                  x=x[train.index,],stepno=300,penalty=100)
```
# mean partial log-likelihood for test set in every boosting step

```r
step.logplik <- predict(cbfit,newdata=x[test.index,],
    newtime=obs.time[test.index],
    newstatus=status[test.index],
    at.step=0:300,type="logplik")
```

```r
plot(step.logplik)
```

# names of covariates with non-zero coefficients at boosting step
# with maximal test set partial log-likelihood

```r
print(cbfit$xnames[cbfit$coefficients[which.max(step.logplik)],] != 0])
```

---

### predict.iCoxBoost

**Predict method for iCoxBoost fits**

**Description**

Obtains predictions at specified boosting steps from an iCoxBoost object fitted by `iCoxBoost`.

**Usage**

```r
## S3 method for class 'iCoxBoost'
predict(object,newdata=NULL, subset=NULL,at.step=NULL,times=NULL, type=c("lp","logplik","risk","CIF"),...)
```

**Arguments**

- **object**
  - fitted CoxBoost object from a `CoxBoost` call.

- **newdata**
  - data frame with new covariate values (for \( n \) new observations). If just prediction for the training data is wanted, it can be omitted. If the predictive partial log-likelihood is wanted (`type=logplik`), this frame also has to contain the response information.

- **subset**
  - an optional vector specifying a subset of observations to be used for evaluation.

- **at.step**
  - scalar or vector of boosting step(s) at which prediction is wanted. If `type="risk"` is used, only one step is admissible. If no step is given, the final boosting step is used.

- **times**
  - vector with \( T \) time points where prediction is wanted. Only needed for `type="risk"`

- **type**
  - type of prediction to be returned: "lp" gives the linear predictor, "logplik" the partial log-likelihood, "risk" the predicted probability of not yet having had the event at the time points given in `times`, and "CIF" the predicted cumulative incidence function, i.e., the predicted probability of having had the event of interest.

- **...**
  - miscellaneous arguments, none of which is used at the moment.
**Value**

For type="lp" and type="logplik" a vector of length n.new (at.step being a scalar) or a n.new * length(at.step) matrix (at.step being a vector) with predictions is returned. For type="risk" or type="CIF" a n.new * T matrix with predicted probabilities at the specific time points is returned.

**Author(s)**

**Examples**

```r
n <- 200; p <- 100
beta <- c(rep(1,2),rep(0,p-2))
x <- matrix(rnorm(n*p),n,p)
actual.data <- as.data.frame(x)
real.time <- -(log(runif(n)))/(10*exp(x %% beta))
cens.time <- rexp(n,rate=1/10)
actual.data$status <- ifelse(real.time <= cens.time,1,0)
actual.data$time <- ifelse(real.time <= cens.time,real.time,cens.time)

# define training and test set
train.index <- 1:100
test.index <- 101:200

# Fit a Cox proportional hazards model by iCoxBoost
cbfit <- iCoxBoost(Surv(time,status) ~ .,data=actual.data[train.index,],
                   stepno=300,cv=FALSE)

# mean partial log-likelihood for test set in every boosting step
step.logplik <- predict(cbfit,newdata=actual.data[test.index,],
                        at.step=0:300,type="logplik")
plot(step.logplik)

# names of covariates with non-zero coefficients at boosting step
# with maximal test set partial log-likelihood
print(coef(cbfit,at.step=which.max(step.logplik)-1))
```
