Package ‘FAOSTAT’

June 2, 2015

Type Package
Title Download Data from the FAOSTAT Database of the Food and Agricultural Organization (FAO) of the United Nations
Version 2.0
Date 2015-05-28
Author Michael C. J. Kao <michael.kao@fao.org>, Markus Gesmann, Filippo Gheri
Maintainer Filippo Gheri <filippo.gheri@fao.org>
Description A list of functions to download statistics from FAOSTAT (database of the Food and Agricultural Organization of the United Nations) and WDI (database of the World Bank), and to perform some harmonization operations.
URL https://github.com/mkao006/FAOSTATpackage
Imports RJSONIO (>= 0.96-0), plyr (>= 1.7.1), data.table (>= 1.8.2),

FAOSTAT-package  
A complementary package to the FAOSTAT database and the Statistical Yearbook of the Food and Agricultural Organization of the United Nations.

Description

A complementary package to the FAOSTAT database and the Statistical Yearbook of the Food and Agricultural Organization of the United Nations.

Author(s)

Michael. C. J. Kao <michael.kao@fao.org>
**Aggregation**

**Compute Aggregates**

---

**Description**

The function takes a relational data frame and computes the aggregation based on the relation specified.

**Usage**

```r
Aggregation(data, aggVar, weightVar = rep(NA, length(aggVar)),
            year = "Year", relationDF = FAOcountryProfile[, c("FAOST_CODE", "M49_FAOST_CODE")],
            aggMethod = rep("sum", length(aggVar)),
            applyRules = TRUE, keepUnspecified = TRUE, unspecifiedCode = 0,
            thresholdProp = rep(0.65, length(aggVar)))
```

**Arguments**

- `aggVar`: The vector of names of the variables to be aggregated.
- `weightVar`: The vector of names of the variables to be used as weighting when the aggregation method is weighted.
- `year`: The column containing the time information.
- `data`: The data frame containing the country level data.
- `relationDF`: A relational data frame which specifies the territory and the mother country. At least one column must have a correspondent variable name in the dataset.
- `aggMethod`: Can be a single method for all data or a vector specifying different method for each variable. The method can be "sum", "mean", "weighted.mean".
- `unspecifiedCode`: The output code of the unspecified group.
- `thresholdProp`: The vector of the missing threshold for the aggregation rule to be applied. The default is set to only compute aggregation if there are more than 65 percent of country must report data (0.65).
- `applyRules`: Logical, specifies whether the thresholdProp rule must be applied or not.
- `keepUnspecified`: Whether countries with unspecified region should be aggregated into an "Unspecified" group or simply drop. Default to create the new group.

**Details**

The length of `aggVar`, `aggMethod`, `weightVar`, `thresholdProp` must be the same. Aggregation should not be computed if insufficient countries have reported data. This corresponds to the argument `thresholdProp` which specifies the percentage which of country must report data (both for the variable to be aggregated and the weighting variable).
chConstruct

Description

A function for constructing year to year change

Usage

chConstruct(data, origVar, country = "FAOST_CODE", year = "Year", newVarName = NA, n = 1)

Arguments

origVar The variable in which the year to year change is to be calculated
country The column representing the index of country.
year The column representing the index of year.
data The data frame containing the data
newVarName The name assigned to the new variable, if missing then .CH will be appended.
n The period for the change rate to be calculated.

Value

A data frame containing the computed year to year change rate.
chgr

Absolute change between the year

Description

Function for generating the n-period absolute change

Usage

chgr(x, n = 1)

Arguments

x
The time series for the change to be calculated.

n
The period for the growth to be calculated over.

Details

In order to ensure the change calculated is reliable, the following rule are applied.

1. 50% of the data must be present.
2. The length of the time series must be greater than n

Otherwise the growth will not be computed.

Value

The n-period change of the time series.

Examples

test.ts <- abs(rnorm(100))
chgr(test.ts, 1)
chgr(test.ts, 3)
chgr(test.ts, 10)
constructSYB

Description

This function avoids double counting of China.

Usage

CHMT(var, data, year = "Year")

Arguments

var The variables that require to be sanitized.
data The data frame which contains the data
year The column which correspond to the year.

Details

We decide to use the smaller subsets in the regional level because weighting variable may not exist for other variables for the larger subsets.

The function only work for FAOST_CODE, if the country coding system is not in FAOST_CODE then use the translateCountryCode function to translate it.

constructSYB

Description

A function used to construct new variables from existing variables.

Usage

constructSYB(data, origVar1, origVar2, newVarName = NA,
               constructType = c("share", "growth", "change", "index"), grFreq = 1,
               grType = c("ls", "geo"), baseYear = 2000)
Arguments

data The data frame containing the raw variable
origVar1 The variable name to be used in construction, refer to Details for more information and usage.
origVar2 The variable name to be used in construction, refer to Details for more information and usage.
newVarName The name assigned to the new variable, if missing then .SC/.SH/.GR/.CH will be appended depending on the type of construction
constructType The type of construction, refer to Details for more information.
grFreq The frequency for the growth rate to be computed.
grType The method for the growth to be calculated, currently supports least squares and geometric.
baseYear The base year to be used for constructing index.

Details

Currently two types of construction are supported, either share or growth rate computation. Share can be a share of total or share of another variable depending on whether an additional variable is supplied or not.

Value

A data frame containing both the original data frame and the processed data and also a list indicating whether the construction passed or failed.

ebind A function to bind the different entity level.

Description

A data frame is chosen over the list is solely for the purpose of transition to ggplot2.

Usage

ebind(territory = NULL, subregion = NULL, region = NULL, world = NULL)

Arguments

territory The data frame which contains the territory/country level data
subregion The sub aggregated region aggregate
region The macro region aggregate
world The world aggregate
FAOcheck  

This function perform some check on the data

Description

The function only works for FAOST_CODE. If the country coding system is not in FAOST_CODE then use the translateCountryCode function to translate it.

Usage

FAOcheck(var, year = "Year", data, type = c("overlap", "multiChina"),  
take = c("simpleCheck", "takeNew", "takeOld", "complete"))

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>var</td>
<td>The variable to be checked.</td>
</tr>
<tr>
<td>year</td>
<td>The column which index the time.</td>
</tr>
<tr>
<td>data</td>
<td>The data frame.</td>
</tr>
<tr>
<td>type</td>
<td>The type of check.</td>
</tr>
<tr>
<td>take</td>
<td>The type of check/replacement to be done in case of type equals to overlap.</td>
</tr>
</tbody>
</table>

Examples

```r
# test.df =  
# data.frame(FAOST_CODE = rep(c(51,167,199), each = 3),  
# Year = rep(c(1990:1992), 3),  
# Value = c(c(3,4,4), c(2,2,2), c(1,2,NA))  
# FAOcheck(var = "Value", data = test.df, type = "overlap", take = "simpleCheck")  
# FAOcheck(var = "Value", data = test.df, type = "overlap", take = "takeNew")  
# FAOcheck(var = "Value", data = test.df, type = "overlap", take = "takeOld")  
# FAOcheck(var = "Value", data = test.df, type = "overlap", take = "complete")
```

FAOcountryProfile  

Country profile

Description

The country profile containing the codes and names of countries.
**FAOmetaTable**  
*The search tree for FAOSTAT*

**Description**

A table containing the relationship between the domain, element, item codes for downloading data from the FAOSTAT API.

**FAOregionProfile**  
*Regional profile*

**Description**

Region profile containing the codes, names and regional classifications of countries.

**FAOsearch**  
*A function to find the domain, element and item code for a specific FAOSTAT query.*

**Description**

A function to find the domain, element and item code for a specific FAOSTAT query.

**Usage**

```r
FAOsearch()
```

**fillCountryCode**  
*A function to get country code when not available in data.*

**Description**

This function can be useful when a dataset provided does not have a country code available.

**Usage**

```r
fillCountryCode(country, data, outCode = "FAOST_CODE")
```

**Arguments**

- `country`: The column name of the data which contains the country name
- `data`: The data frame to be matched
- `outCode`: The output country code system, defaulted to FAO standard.
Description

Function for generating the n-period rolling geometric growth rate.

Usage

geogr(x, n = 1)

Arguments

x The time series for the growth rate to be calculated.
n The period for the growth to be calculated over.

Details

In order to ensure the growth rate calculated is reliable, the following rule are applied.

1. 50% of the data must be present.
2. The length of the time series must be greater than n

Otherwise the growth will not be computed.

Value

The n-period geometric growth rate of the time series.

Examples

test.ts = abs(rnorm(100))
geogr(test.ts, 1)
geogr(test.ts, 3)
geogr(test.ts, 10)
getFAO

Access to FAO FAOSTAT API.

Description

A function to access FAOSTAT data through the FAOSTAT API.

Usage

getFAO(name = NULL, domainCode = "RL", elementCode = 5110, itemCode = 6621, query, printURL = FALSE, useCHMT = TRUE, outputFormat = "wide", returnNames = FALSE, returnFlags = FALSE, yearRange = NULL, countrySet = NULL)

Arguments

name The name to be given to the variable.
domainCode The domain of the data.
elementCode The code of the element.
itemCode The code of the specific item.
yearRange A numeric vector containing the years to be downloaded.
countrySet The FAOSTAT codes of those countries to be downloaded.
query The object created if using the FAOsearch function.
printURL Whether the url link for the data should be printed.
useCHMT logical, whether the CHMT function should be applied to avoid double counting of China.
outputFormat The format of the data, can be 'long' or 'wide'.
returnNames Logical, should the area, the element and the item names be reported?.
returnFlags Logical, whether the flags should be returned. Only work with outputFormat long.

Details

Need to account for multiple itemCode, currently only support one single variable.

Value

Outputs a data frame containing the specified data.

See Also

getWDI, getWDItoSYB, getFAOtoSYB, FAOsearch
getFAOtoSYB  

Access to FAO FAOSTAT API

Description
A wrapper function using getFAO() to obtain and process multiple data set to obtain data.

Usage
getFAOtoSYB(name = NULL, domainCode = "RL", elementCode = 5110,
  itemCode = 6621, query, printURL = FALSE, useCHMT = TRUE,
  yearRange = NULL, countrySet = NULL, outputFormat = c("wide", "long"),
  returnFlags = FALSE)

Arguments
- name: The name to be given to the variable.
- domainCode: The domain code of the variable, see details.
- elementCode: The element code of the variable, see details.
- itemCode: The item code of the variable, see details.
- query: The object created if using the FAOsearch function.
- printURL: Whether the url link for the data should be printed.
- useCHMT: Logical, whether the CHMT function should be applied to avoid double counting of China.
- outputFormat: The format of the data, can be 'long' or 'wide'.
- returnFlags: Logical, whether the flags should be returned. Only work with outputFormat long.
- yearRange: A numeric vector containing the years to be downloaded.
- countrySet: The FAOSTAT codes of those countries to be downloaded.

Value
A list containing the following elements
- entity: The entity level data
- aggregates: The aggregates provided by the FAO
- results: The status of the download, whether success/failed

See Also
getWDI, getFAO, getWDItoSYB

Examples
```r
# The default option is the arable land area
# arlLand.lst = getFAOtoSYB()
```
getWDI

Access to World Bank WDI API

Description

A function to extract data from the World Bank API

Usage

```r
getWDI(indicator = "SP.POP.TOTL", name = NULL, startDate = 1960, 
endDate = format(Sys.Date(), "%Y"), printURL = FALSE, 
outputFormat = "wide")
```

Arguments

- `indicator` The World Bank official indicator name.
- `name` The new name to be used in the column.
- `startDate` The start date for the data to begin
- `endDate` The end date.
- `printURL` Whether the url link for the data should be printed
- `outputFormat` The format of the data, can be 'long' or 'wide'.

Details

Value

A data frame containing the desired World Bank Indicator

See Also

`getFAO, getWDItosYB, getFAOtoSYB`

Examples

```r
## pop.df = getWDI()
```
getWDImetaData  World Bank Indicator Metadata

Description

A function to extract the definition and the meta data from the World Bank API.

Usage

getWDImetaData(indicator, printMetaData = FALSE, saveMetaData = FALSE, saveName = "worldBankMetadata")

Arguments

indicator     The World Bank official indicator name.
printMetaData logical, print out the meta data information
saveMetaData  logical, whether meta data should be saved as a local csv file.
saveName      The name of the file for the meta data to save to.

Examples

## pop.df = getWDImetaData("SP.POP.TOTL",
##     printMetaData = TRUE, saveMetaData = TRUE)

getWDItoSYB  Access to World Bank WDI API

Description

The function downloads data from the World Bank API.

Usage

getiWDItoSYB(indicator = "SP.POP.0014.T0.ZS", name = NULL,
            startDate = 1960, endDate = format(Sys.Date(), "%Y"), printURL = FALSE,
            getMetaData = TRUE, printMetaData = FALSE, saveMetaData = FALSE,
            outputFormat = c("wide", "long"))
Arguments

name          The new name to be used in the column.
indicator     The World Bank official indicator name.
startDate     The start date for the data to begin
endDate       The end date.
printURL      Whether the url link for the data should be printed
getMetaData   Whether the data definition and the meta data should be downloaded as well.
printMetaData logical, print out the meta data information
saveMetaData  logical, whether meta data should be saved as a local csv file
outputFormat  The format of the data, can be 'long' or 'wide'.

Value

A list containing the following elements

data  The country level data
aggregates The aggregates provided by the World Bank
metaData The metaData associated with the data
results The status of the download, whether success/failed

See Also

getWDI, getFAO, getFAOtoSYB

Examples

```r
## pop.df = getWDItoSYB(name = "total_population",
##                        indicator = "SP.POP.TOTL")
```

Description

A function for constructing growth rate variables.

Usage

grConstruct(data, origVar, newVarName = NA, type = c("geo", "ls", "ch"),
            n = 1)
**Arguments**

- **data**
  The data frame containing the data

- **origVar**
  The variable in which the growth is to be calculated

- **newVarName**
  The name assigned to the new variable, if missing then .SC/.SH/.GR will be appended depending on the type of construction.

- **type**
  The type of growth rate, can be least squares or geometric

- **n**
  The period for the growth rate to be calculated (Refer to the lsgr or the geogr functions.)

**Value**

A data frame containing the computed growth rate.

**Examples**

```r
test.df2 = data.frame(FAOST_CODE = rep(c(1, 5000), each = 5),
                      Year = rep(1990:1994, 2),
                      a = rep(1:5, 2), b = rep(1:5, 2))
grConstruct(test.df2, origVar = "a", type = "geo", n = 1)
grConstruct(test.df2, origVar = "a", type = "geo", n = 3)
grConstruct(test.df2, origVar = "a", type = "geo", n = 5)
```

---

**indConstruct**

*Construct indices*

**Description**

A function for constructing indices

**Usage**

```r
indConstruct(data, origVar, newVarName = NA, baseYear = 2000)
```

**Arguments**

- **data**
  The data frame containing the data

- **origVar**
  The variable in which the indices is to be computed

- **newVarName**
  The name assigned to the new variable, if missing then .SC/.SH/.GR/.CH/.IND will be appended depending on the type of construction.

- **baseYear**
  The year which will serve as the base

**Value**

The indice
**lsgr**

**Examples**

```
test.df = data.frame(FAOST_CODE = rep(1, 100), Year = 1901:2000, 
                      test = 1:100)
indConstruct(test.df, origVar = "test", baseYear = 1950)
```

---

**Description**

Function for generating the n-period rolling least squares growth rate.

**Usage**

```
lsgr(x, n = 1)
```

**Arguments**

- **x**: The time series for the growth rate to be calculated
- **n**: The period for the growth to be calculated over.

**Details**

Missing values are omitted in the regression. (Will need to check this.)

TODO (Michael): There is still some error associated with this function, will need to investigate further. Will need a rule for this, when the fluctuation is large and data are sufficient then take the lsgr, otherwise the geogr.

In order to ensure the growth rate calculated is reliable, the following rule are applied.

1. 50% of the data must be present.
2. The length of the time series must be greater than n.

Otherwise the growth will not be computed.

**Value**

The n-period least squares growth rate of the time series

**Examples**

```
test.ts = abs(rnorm(100))
lsgr(test.ts, 1)
lsgr(test.ts, 3)
lsgr(test.ts, 10)
```
**mergeSYB**

*Function for merging data from different source.*

**Description**

This function searches for supported country system and translate the data to allow for join.

**Usage**

```r
mergeSYB(x, y, outCode = "FAOST_CODE", all = TRUE, ...)
```

**Arguments**

- `x` : data frames, or objects to be coerced to one.
- `y` : data frames, or objects to be coerced to one.
- `outCode` : The country code system to be used to join the different sources.
- `all` : Same as the merge function, defaulted to an outer join.
- `...` : Arguments to be passed on to the merge function.

**Details**

The names of the data to be merged has to be the same as the FAOcountryProfile code name.

---

**overlap**

*This function checks whether there are overlapping between the transitional countries.*

**Description**

This function checks whether there are overlapping between the transitional countries.

**Usage**

```r
overlap(old, new, var, year = "Year", data, take)
```

**Arguments**

- `old` : The FAOST_CODE of the old countries
- `new` : The FAOST_CODE of the new countries
- `var` : The variable to be checked
- `year` : The column which index the time.
- `data` : The data frame
- `take` : The type of check/replacement to be done.
**printLab**

*Print labels*

**Description**

A function to print standardised formatted labels without having messy codes in the functions.

**Usage**

`printLab(label, span = FALSE, width = getOption("width"))`

**Arguments**

- `label`: The label to be printed
- `span`: Whether the dash should span the whole width of the screen (80 characters)
- `width`: The width of the screen.

**Value**

The formatted print

---

**scaleUnit**

*A function to standardize the unit*

**Description**

The function standardize the data to the desirable unit when the multiplier vector is supplied. For example per 1000 people is scaled to per person by supplying a multiplier of 1000.

**Usage**

`scaleUnit(df, multiplier)`

**Arguments**

- `df`: The data frame containing the data to be scale
- `multiplier`: The named vector with the multiplier to be scaled. The name is mandatory in order for the function to identify the variable in the data frame. A data.frame can also be supplied with the first column being the name and the second being the numeric multiplier.
Examples

```r
## Create the data frame
test.df = data.frame(FAOST_CODE = 1:5, Year = 1995:1999,
 var1 = 1:5, var2 = 5:1)

## Create the named vector for scaling
multiplier = c(1, 10)
names(multiplier) = c("var1", "var2")

## Scale the data
scaleUnit(test.df, multiplier = multiplier)
```

```
shConstruct    Construct share variable

Description
A function for constructing the share of a variable of an aggregated variable.

Usage
shConstruct(data, totVar, shareVar, newVarName = NA)

Arguments
data          The data frame containing both the share variable and the aggregated variable
totVar        The aggregated variable.
shareVar      The subset of the aggregated variable which to be divided by.
newVarName    The name assigned to the new variable, if missing then .SC/.SH/.GR will be appended depending on the type of construction

Details
The share of a variable can be share of the World (if additional variable were not supplied) or share of another variable (per Capita if population was supplied).

Value
A data frame with the new constructed variable

Examples
```
## Total variables provided, scale by totVar
test.df = data.frame(FAOST_CODE = 1, Year = 1990:1994, a = 1:5, b = 1:5)
shConstruct(data = test.df, totVar = "a", shareVar = "b")

## Total variables not provided, scale by world aggregate.
test.df2 = data.frame(FAOST_CODE = rep(c(1, 5000), each = 5),
```

translateCountryCode  A function to translate between different country coding systems

Description
The function translate any country code scheme to another if both are in the FAOcountryProfile

Usage
translateCountryCode(data, from, to, oldCode)

Arguments
- data  The data frame
- from  The name of the old coding system
- to    The name of the new coding system
- oldCode  The column name of the old country coding scheme

translateUnit  Function to translate multipliers

Description
This function translates number to character name or vice versa

Usage
translateUnit(vec)

Arguments
- vec  The vector containing name or number to be translated

Examples
## Create numeric vector
myUnit = c(1000, 1e6, 1000, 1e9, 1e9, 1e12)

## Translate numeric to character
myUnit2 = translateUnit(myUnit)
myUnit2

## Now translate back
translateUnit(myUnit2)
