Package ‘FindIt’

August 24, 2017

Version 1.1.1
Date 2017-08-23
Title Finding Heterogeneous Treatment Effects
Author Naoki Egami <negami@princeton.edu>, Marc Ratkovic <ratkovic@princeton.edu>, Kosuke Imai <kimai@princeton.edu>,
Maintainer Naoki Egami <negami@princeton.edu>
Depends R (>= 3.1.0), arm
Imports glmnet, lars, Matrix, quadprog, ggplot2, glinternet, igraph, sandwich, lmtest, stats, graphics, utils
Description The heterogeneous treatment effect estimation procedure proposed by Imai and Ratkovic (2013)<DOI: 10.1214/12-AOAS593>. The proposed method is applicable, for example, when selecting a small number of most (or least) efficacious treatments from a large number of alternative treatments as well as when identifying subsets of the population who benefit (or are harmed by) a treatment of interest. The method adapts the Support Vector Machine classifier by placing separate LASSO constraints over the pre-treatment parameters and causal heterogeneity parameters of interest. This allows for the qualitative distinction between causal and other parameters, thereby making the variable selection suitable for the exploration of causal heterogeneity. The package also contains a class of functions, CausalANOVA, which estimates the average marginal interaction effects (AMIEs) by a regularized ANOVA as proposed by Egami and Imai (2016+). It contains a variety of regularization techniques to facilitate analysis of large factorial experiments.

Description

This data set gives the outcomes as well as treatment assignments of the conjoint analysis in Carlson (2015). Please Carlson (2015) and Egami and Imai (2016+) for more details.

Format

A data frame consisting of 7 columns (including a treatment assignment vector) and 3232 observations.

CausalANOV A

Estimating the AMEs and AMIEs with the CausalANOV A.

Description

CausalANOV A estimates coefficients of the specified ANOVA with regularization. By taking differences in coefficients, the function recovers the AMEs and AMIEs.

Usage

CausalANOV A(formula, int2.formula = NULL, int3.formula = NULL, data, nway = 1, pair.id = NULL, diff = FALSE, screen = FALSE, screen.type = "fixed", screen.num.int = 3, collapse = FALSE, collapse.type = "fixed", collapse.cost = 0.3, family = "binomial", cluster = NULL, maxIter = 50, eps = 1e-05, fac.level = NULL, ord.fac = NULL, select.prob = FALSE, boot = 100, seed = 1234, verbose = TRUE)

Arguments

formula A formula that specifies outcome and treatment variables.
int2.formula (optional). A formula that specifies two-way interactions.
int3.formula (optional). A formula that specifies three-way interactions.
data An optional data frame, list or environment (or object coercible by 'as.data.frame' to a data frame) containing the variables in the model. If not found in 'data', the variables are taken from 'environment(formula)', typically the environment from which 'CausalANOV A' is called.
nway With nway=1, the function estimates the Average Marginal Effects (AMEs) only. With nway=2, the function estimates the AMEs and the two-way Average Marginal Interaction Effects (AMIEs). With nway=3, the function estimates the AMEs, the two-way and three-way AMIEs. Default is 1.
pair.id (optional). Unique identifiers for each pair of comparison. This option is used when diff=TRUE.
diff A logical indicating whether the outcome is the choice between a pair. If diff=TRUE, pair.id should specify a pair of comparison. Default is FALSE.
screen A logical indicating whether select significant factor interactions with glinternet. When users specify interactions using int2.formula or int3.formula, this option is ignored. screen should be used only when users want data-driven selection of factor-interactions. With screen.type, users can specify how to screen factor interactions. We recommend to use this option when the number of factors is large, e.g., more than 6. Default is FALSE.
screen.type Type for screening factor interactions. (1) "fixed" select the fixed number (specified by screen.num.int) of factor interactions. (2) "cv.min" selects factor-interactions with the tuning parameter giving the minimum cross-validation
error. (3) "cv.1Std" selects factor-interactions with the tuning parameter giving a cross-validation error that is within 1 standard deviation of the minimum cv error.

`screen.num.int` (optional). The number of factor interactions to select. This option is used when and `screen=TRUE` and `screen.type="fixed"`. Default is 3.

`collapse` A logical indicating whether to collapse insignificant levels within factors. With `collapse.type`, users can specify how to collapse levels within factors. We recommend to use this option when the number of levels is large, e.g., more than 6. Default is FALSE.

`collapse.type` Type for collapsing levels within factors. (1) "fixed" collapses levels with the fixed cost parameter (specified by `collapse.cost`). (2) "cv.min" collapses levels with the cost parameter giving the minimum cross-validation error. This option might take time. (3) "cv.1Std" collapses with the cost parameter giving a cross-validation error that is within 1 standard deviation of the minimum cv error. This option might take time.

`collapse.cost` (optional). A cost parameter ranging from 0 to 1. 1 corresponds to no collapsing. The closer to 0, the stronger regularization. Default is 0.3.

`family` A family of outcome variables. "gaussian" when continuous outcomes "binomial" when binary outcomes. Default is "binomial".

`cluster` Unique identifies with which cluster standard errors are computed.

`maxIter` The number of maximum iteration for `glmnet`.

`eps` A tolerance parameter in the internal optimization algorithm.

`fac.level` (optional). A vector containing the number of levels in each factor. The order of `fac.level` should match to the order of columns in the data. For example, when the first and second columns of the design matrix is "Education" and "Race", the first and second element of `fac.level` should be the number of levels in "Education" and "Race", respectively.

`ord.fac` (optional). Logical vectors indicating whether each factor has ordered (TRUE) or unordered (FALSE) levels. When levels are ordered, the function uses the order given by function `levels()`. If levels are ordered, the function places penalties on the differences between adjacent levels. If levels are unordered, the function places penalties on the differences based on every pairwise comparison.

`select.prob` (optional). A logical indicating whether selection probabilities are computed. This option might take time.

`boot` The number of bootstrap replicates for `select.prob`. Default is 50.

`seed` Seed for bootstrap.

`verbose` Whether it prints the value of a cost parameter used.

**Details**

**Regularization:** `screen` and `collapse`.

Users can implement regularization in order to reduces false discovery rate and facilitates interpretation. This is particularly useful when analyzing factorial experiments with a large number of factors, each having many levels.
• When `screen=TRUE`, the function selects significant factor interactions with `glinternet` (Lim and Hastie 2015) before estimating the AMEs and AMIEs. This option is recommended when there are many factors, e.g., more than 6 factors. Alternatively, users can pre-specify interactions of interest using `int2.formula` and `int3.formula`.

• When `collapse=TRUE`, the function collapses insignificant levels within each factor by `GashANOVA` (Post and Bondell 2013) before estimating the AMEs and AMIEs. This option is recommended when there are many levels within some factors, e.g., more than 6 levels.

**Inference after Regularization:**

• When `screen=TRUE` or `collapse=TRUE`, in order to make valid inference after regularization, we recommend to use `test.CausalANOVA` function. It takes the output from `CausalANOVA` function and estimate the AMEs and AMIEs with `newdata` and provide confidence intervals. Ideally, users should split samples into two; use a half for regularization with `CausalANOVA` function and use the other half for inference with `test.CausalANOVA`.

• If users do not need regularization, specify `screen=FALSE` and `collapse=FALSE`. The function estimates the AMEs and AMIEs and compute confidence intervals with the full sample.

**Suggested Workflow:** (See Examples below as well)

1. Specify the order of levels within each factor using `levels()`. When `collapse=TRUE`, the function places penalties on the differences between adjacent levels when levels are ordered, it is crucial to specify the order of levels within each factor carefully.

2. Run `CausalANOVA`.
   
   (a) Specify `formula` to indicate outcomes and treatment variables and `nway` to indicate the order of interactions.
   (b) Specify `diff=TRUE` and `pair.id` if the outcome is the choice between a pair.
   (c) Specify `screen`. `screen=TRUE` to implement data-driven selection of factor interactions. `screen=FALSE` to specify interactions through `int2.formula` and `int3.formula` by hand.
   (d) Specify `collapse`. `collapse=TRUE` to implement data-driven collapsing of insignificant levels. `collapse=FALSE` to use the original number of levels.

3. Run `test.CausalANOVA` when `select=TRUE` or `collapse=TRUE`.

4. Run `summary` and `plot` to explore the AMEs and AMIEs.

5. Estimate conditional effects using `ConditionalEffect` function and visualize them using `plot` function.

**Value**

<table>

## AMEs and two-way AMIEs

fit2 <- CausalANOVA(formula=won ~ newRecordF + promise + coeth_voting + relevantdegree,
    int2.formula = ~ newRecordF:coeth_voting,
    data=Carlson, pair.id=Carlson$contestresp, diff=TRUE,
    cluster=Carlson$rescode5, nway=2)
summary(fit2)
Estimating the Conditional Effects with the CausalANOVA.

Description

ConditionalEffect estimates a variety of conditional effects using the output from CausalANOVA.
Usage

ConditionalEffect(object, treat.fac = NULL, cond.fac = NULL, base.ind = 1, round = 3, inference = NULL, verbose = TRUE)

Arguments

- **object**: The output from CausalANOVA function.
- **treat.fac**: The name of factor acting as the main treatment variable.
- **cond.fac**: The name of factor acting as the conditioning (moderating) variable.
- **base.ind**: An indicator for the baseline of the treatment factor. Default is 1.
- **round**: Digits to round estimates. Default is 3.
- **inference**: (optional). This argument is mainly for internal use. It indicates whether CausalANOVA has done inference or not.
- **verbose**: Whether it prints the progress.

Details

See Details in CausalANOVA.

Value

- **ConditionalEffects**: The summary of estimated conditional effects.
- **...**: Arguments for the internal use.

\begin{flushleft}
\textbf{cv.CausalANOVA} \hspace{1cm} \textit{Cross validation for the CausalANOVA.}
\end{flushleft}

Description

cv.CausalANOVA implements cross-validation for CausalANOVA to select the collapse.cost parameter. CausalANOVA runs this function internally when defaults when collapse.type=cv.min or collapse.type=cv.1Std.

Usage

cv.CausalANOVA(formula, int2.formula = NULL, int3.formula = NULL, data,
  nway = 1, pair.id = NULL, diff = FALSE, cv.collapse.cost = c(0.1, 0.3, 0.7), nFolds = 5,
  screen = FALSE, screen.type = "fixed", screen.num.int = 3, family = "binomial",
  cluster = NULL, maxIter = 50, eps = 1e-05, seed = 1234, fac.level = NULL, ord.fac = NULL,
  verbose = TRUE)

Arguments

- formula: a formula that specifies outcome and treatment variables.
- int2.formula: (optional). A formula that specifies two-way interactions.
cv.CausalANOVA

**data**

an optional data frame, list or environment (or object coercible by 'as.data.frame' to a data frame) containing the variables in the model. If not found in 'data', the variables are taken from 'environment(formula)', typically the environment from which 'CausalANOVA' is called.

**nway**

With nway=1, the function estimates the Average Marginal Effects (AMEs) only. With nway=2, the function estimates the AMEs and the two-way Average Marginal Interaction Effects (AMIEs). With nway=3, the function estimates the AMEs, the two-way and three-way AMIEs. Default is 1.

**pair.id**

(optional). Unique identifiers for each pair of comparison. This option is used when diff=TRUE.

**diff**

A logical indicating whether the outcome is the choice between a pair. If diff=TRUE, pair.id should specify a pair of comparison. Default is FALSE.

**cv.collapse.cost**

A vector containing candidates for a cost parameter ranging from 0 to 1. 1 corresponds to no regularization and the smaller value corresponds to the stronger regularization. Default is c(0.1, 0.3, 0.7).

**n folds**

number of folds - default is 5. Although nfolds can be as large as the sample size (leave-one-out CV), it is not recommended for large datasets.

**screen**

A logical indicating whether select significant factor interactions with glinternet. When users specify interactions using int2.formula or int3.formula, this option is ignored. screen should be used only when users want data-driven selection of factor-interactions. With screen.type, users can specify how to screen factor interactions. We recommend to use this option when the number of factors is large, e.g., more than 6. Default is FALSE.

**screen.type**

Type for screening factor interactions. (1) "fixed" select the fixed number (specified by screen.num.int) of factor interactions. (2) "cv.min" selects factor-interactions with the tuning parameter giving the minimum cross-validation error. (3) "cv.1std" selects factor-interactions with the tuning parameter giving a cross-validation error that is within 1 standard deviation of the minimum cv error.

**screen.num.int**

(optional). The number of factor interactions to select. This option is used when and screen=TRUE and screen.type="fixed". Default is 3.

**family**

A family of outcome variables. "gaussian" when continuous outcomes "binomial" when binary outcomes. Default is "binomial".

**cluster**

Unique identifies with which cluster standard errors are computed.

**maxIter**

The number of maximum iteration for glinternet.

**eps**

A tolerance parameter in the internal optimization algorithm.

**seed**

an argument for set.seed().

**fac.level**

optional. A vector containing the number of levels in each factor. The order of fac.level should match to the order of columns in the data. For example, when the first and second columns of the design matrix is "Education" and "Race", the first and second element of fac.level should be the number of levels in "Education" and "Race", respectively.

ord.fac  

optional. logical vectors indicating whether each factor has ordered (TRUE) or unordered (FALSE) levels. When levels are ordered, the function uses the order given by function levels(). If levels are ordered, the function places penalties on the differences between adjacent levels. If levels are unordered, the function places penalties on the differences based on every pairwise comparison.

verbose  

whether it prints the value of a cost parameter used.

Details

See Details in CausalANOVA.

Value

- cv.error: The mean cross-validated error - a vector of length length(cv.t).
- cv.min: A value of t that gives minimum cv.missclass.
- cv.1Std: The largest value of t such that error is within 1 standard error of the minimum.
- cv.each.mat: A matrix containing cross-validation errors for each fold and cost parameter.
- cv.cost: The cv.collapse.cost used in the function.

## #################################################################
## Collapsing Without Screening
## #################################################################
# FindIt for Estimating Heterogeneous Treatment Effects

## Description

FindIt returns a model with the most predictive treatment-treatment interactions or treatment-covariate interactions.

## Usage

```r
FindIt(model.treat, model.main, model.int, data = NULL, type = "binary", treat.type = "multiple", nway, search.lambdas = TRUE, lambdas = NULL, make.twoway = TRUE, make.allway = TRUE, wts = 1, scale.c = 1, scale.int = 1, fit.glmnet = TRUE, make.reference = TRUE, reference.main = NULL, threshold = 0.999999)
```

## Arguments

- `model.treat`: A formula that specifies outcome and treatment variables.
- `model.main`: An optional formula that specifies pre-treatment covariates to be adjusted.
- `model.int`: A formula specifying pre-treatment covariates to be interacted with treatment assignments when `treat.type="single"`.
- `data`: An optional data frame, list or environment (or object coercible by `as.data.frame`) to a data frame containing the variables in the model. If not found in 'data', the variables are taken from 'environment(formula)', typically the environment from which 'FindIt' is called.
- `type`: "binary" for a binary outcome variable, which needs to be integer class; "continuous" for a continuous outcome variable.
- `treat.type`: "single" for interactions between a single treatment variable, which needs to be integer class, and multiple pre-treatment covariates specified with `model.int`; "multiple" is used when treatment-treatment interactions are of interest and treat is a matrix of multiple treatments.
- `nway`: An argument passed to `makeallway` when `treat.type="multiple"`. FindIt generates treatment-treatment interactions up to the order specified with this argument. In general, it is recommended to use the number of factorial treatments. The current version covers up to four way interactions.
search.lambda\(s\) Whether to search for the tuning parameters for the LASSO constraints. If FALSE, lambdas must be supplied.

lambdas Tuning parameters to be given to findIt; only used if search.lambda\(s\) = FALSE.

make.twoway If make.twoway = TRUE, all possible two-way interactions for the pre-treatment covariates specified in model.main and model.int are generated within findIt. The default is set to be TRUE.

make.allway If make.allway = TRUE, all possible treatment-treatment interactions for multiple treatments are generated when treat.type = "multiple". Interactions of the order up to the value of nway is computed.

wts An optional set of scaling weights. The default is 1.

scale.c A set of weights for recaling the pre-treatment covariates; only used if make.twoway = FALSE. maketwoway is useful for generating these.

scale.int A set of weights for recaling the covariates to be interacted with treatment variables; only used if make.twoway = FALSE. maketwoway is useful for generating these.

fit.glmnet Whether to fit using the coordinate descent method in glmnet (TRUE) or the regularization path method of LARS (FALSE).

make.reference Whether to make a reference matrix to check which columns are dropped when makeallway = TRUE.

reference.main If make.allway = FALSE and researchers generate a matrix of all possible interactions between factorial treatments, reference from makeallway function is better to be passed to findIt through this argument.

threshold An argument passed to makeallway when treat.type = "multiple". Threshold to drop correlated columns when makeallway is used.

**Details**

Implements the alternating line search algorithm for estimating the tuning parameters, as described in Imai and Ratkovic (2013).

**Value**

coefs A named vector of scaled coefficients
coefs.orig A vector of coefficients on the original scale, if scale.c and scale.t was used
fit Fitted values on an SVM scale
names.out Names of the coefficients
y A vector of observed outcomes
X.c A matrix of pre-treatment covariates to be adjusted
X.t A matrix of treatments and treatment-treatment interactions, or treatment-covariate interactions
GCV GCV statistic at the minimum
ATE When treat.type = "single", the estimated ATE. When treat.type = "multiple", the estimated treatment effect of each unique treatment combination
lambdas Tuning parameters used for the fit
reference When treat.type="multiple", after making all interaction terms, columns
with no variation or columns perfectly correlated with one of other columns are
automatically dropped. reference shows which columns are kept and dropped.

Description
This data set gives the outcomes as well as treatment assignments and covariates for the NationalSupported Work Study, as analyzed in LaLonde (1986).

Format
A data frame consisting of 12 columns (including a treatment assignment vector) and 2787 observations.

<table>
<thead>
<tr>
<th>outcome</th>

</tbody>
</table>

Source
Data from the National Supported Work Study. A benchmark matching dataset. 1975 earnings are pre-treatment.

References
**plot.PredictFindIt**

Plot estimated treatment effects or predicted outcomes for each treatment combination.

### Description

Plot estimated treatment effects when `treat.type="single"` and predicted outcomes for each treatment combination when `treat.type="multiple"`.

### Usage

```r
## S3 method for class 'PredictFindIt'
plot(x, main, xlab, ylab, ...)
```

### Arguments

- `x`: output from `predict.FindIt`.
- `main`: the argument specifying the main title of the plot.
- `xlab`: the argument specifying the name of x axis.
- `ylab`: the argument specifying the name of y axis.
- `...` further arguments passed to or from other methods.

### Details

Plot estimated treatment effects when `treat.type="single"` and predicted outcomes for each treatment combination when `treat.type="multiple"`.

### Value

`plot` Plot estimated treatment effects when `treat.type="single"` and predicted outcomes for each treatment combination when `treat.type="multiple"`.

### Author(s)

Naoki Egami, Marc Ratkovic and Kosuke Imai.

### Examples

```r
## See the help page for FindIt() for an example.
```
predict.FindIt

Computing predicted values for each sample in the data.

Description

predict.FindIt takes an output from FindIt and returns estimated treatment effects when `treat.type="single"` and predicted outcomes for each treatment combination when `treat.type="multiple"`.

Usage

```r
## S3 method for class 'FindIt'
predict(object, newdata, sort = TRUE, decreasing = TRUE,
         wts = 1, unique = FALSE, ...)
```

Arguments

- **object**: An output object from FindIt.
- **newdata**: An optional data frame in which to look for variables with which to predict. If omitted, the data used in FindIt is used.
- **sort**: Whether to sort samples according to estimated treatment effects.
- **decreasing**: When `sort=TRUE`, whether to sort the output in descending order or not.
- **wts**: Weights.
- **unique**: If `unique=TRUE`, predict returns estimated treatment effects or predicted outcomes for unique samples.
- **...**: further arguments passed to or from other methods.

Details

Useful for computing estimated treatment effects or predicted outcomes for each treatment combination. By using `newdata`, researchers can compute them for any samples.

Value

- **data**: A matrix of estimated treatment effects when `treat.type="single"` and predicted outcomes for each treatment combination when `treat.type="multiple"`.

Author(s)

Naoki Egami, Marc Ratkovic and Kosuke Imai.

Examples

```r
## See the help page for FindIt() for an example.
```
test.CausalANOVA

Estimating the AMEs and AMIEs after Regularization with the CausalANOVA.

Description

test.CausalANOVA estimates the AMEs and AMIEs with confidence intervals after regularization with CausalANOVA function.

Usage

test.CausalANOVA(fit, newdata, collapse.level = TRUE, diff = FALSE, pair.id = NULL, cluster = NULL)

Arguments

- **fit**: The output from CausalANOVA function.
- **newdata**: A data frame to use for re-estimating the AMEs and AMIEs with confidence intervals.
- **collapse.level**: A logical indicating whether to collapse insignificant levels within factors as suggested by the CausalANOVA output users provide.
- **diff**: A logical indicating whether the outcome is the choice between a pair. If diff=TRUE, pair.id should specify a pair of comparison. Default is FALSE.
- **pair.id** (optional). Unique identifiers for each pair of comparison. This option is used when diff=TRUE.
- **cluster**: Unique identifiers with which cluster standard errors are computed.

Details

See Details in CausalANOVA.

Value

- **fit**: The output of class CausalANOVA.

Author(s)

Naoki Egami and Kosuke Imai.
