Abstract

This is a (currently very incomplete) write-up of the many smaller and larger design decisions we have made in organizing functionalities in the Matrix package.

Classes: There’s a rich hierarchy of matrix classes, which you can visualize as a set of trees whose inner (and “upper”) nodes are virtual classes and only the leaves are non-virtual “actual” classes.

Functions and Methods:
- setAs()
- others

1 The Matrix class structures

Take Martin’s DSC 2007 talk to depict class hierarchy.

1.1 Diagonal Matrices

The class of diagonal matrices is worth mentioning for several reasons. First, we have wanted such a class, because multiplication methods are particularly simple with diagonal matrices. The typical constructor is Diagonal() whereas the accessor (as for traditional matrices), diag() simply returns the vector of diagonal entries:

```r
> library(Matrix)
> (D4 <- Diagonal(4, 10*(1:4)))
```

4 x 4 diagonal matrix of class "ddiMatrix"

```
[1,]  10 .  .  .
[2,]  .  20 .  .
[3,]  .  .  30 .
[4,]  .  .  .  40
```
> str(D4)

Formal class 'ddiMatrix' [package "Matrix"] with 4 slots
  ..@ diag : chr "N"
  ..@ Dim : int [1:2] 4 4
  ..@ Dimnames:List of 2
     ..$ : NULL
     ..$ : NULL
  ..@ x : num [1:4] 10 20 30 40

> diag(D4)

[1] 10 20 30 40

We can modify the diagonal in the traditional way (via method definition for diag<-()):

> diag(D4) <- diag(D4) + 1:4
> D4

4 x 4 diagonal matrix of class "ddiMatrix"

[1,] 11 . . .
[2,] . 22 . .
[3,] . . 33 .
[4,] . . . 44

Note that unit-diagonal matrices (the identity matrices of linear algebra) with slot diag = "U" can have an empty x slot, very analogously to the unit-diagonal triangular matrices:

> str(I3 <- Diagonal(3)) ## empty 'x' slot

Formal class 'ddiMatrix' [package "Matrix"] with 4 slots
  ..@ diag : chr "U"
  ..@ Dim : int [1:2] 3 3
  ..@ Dimnames:List of 2
     ..$ : NULL
     ..$ : NULL
  ..@ x : num(0)

> getClass("diagonalMatrix") ## extending "sparseMatrix"

Virtual Class "diagonalMatrix" [package "Matrix"]

Slots:
Name: diag Dim Dimnames
Originally, we had implemented diagonal matrices as dense rather than sparse matrices. After several years it became clear that this had not been helpful really both from a user and programmer point of view. So now, indeed the \textit{diagonalMatrix} class does extend the \textit{sparseMatrix} one. However, we do \textit{not} store explicitly where the non-zero entries are, and the class does \textit{not} extend any of the typical sparse matrix classes, \textit{CsparseMatrix}, \textit{TsparseMatrix}, or \textit{RsparseMatrix}. Rather, the \texttt{diag()}onal (vector) is the basic part of such a matrix, and this is simply the \texttt{x} slot unless the \texttt{diag} slot is \texttt{"U"}, the unit-diagonal case, which is the identity matrix.

Further note, e.g., from the \texttt{?Diagonal} help page, that we provide (low level) utility function \texttt{.sparseDiagonal()} with wrappers \texttt{.symDiagonal()} and \texttt{.trDiagonal()} which will provide diagonal matrices inheriting from \texttt{"CsparseMatrix"} which may be advantageous in some cases, but less efficient in others, see the help page.

## 2 Matrix Transformations

### 2.1 Coercions between Matrix classes

You may need to transform Matrix objects into specific shape (triangular, symmetric), content type (double, logical, ...) or storage structure (dense or sparse). Every useR should use \texttt{as(x, \texttt{<superclass>})} to this end, where \texttt{<superclass>} is a virtual Matrix super class, such as \texttt{"triangularMatrix"}, \texttt{"dMatrix"}, or \texttt{"sparseMatrix"}.

In other words, the user should \textit{not} coerce directly to a specific desired class such as \texttt{"dtCMatrix"}, even though that may occasionally work as well.

Here is a set of rules to which the Matrix developers and the users should typically adhere:

\textbf{Rule 1} : \texttt{as(M, \texttt{"matrix"})} should work for all Matrix objects \texttt{M}.

\textbf{Rule 2} : \texttt{Matrix(x)} should also work for matrix like objects \texttt{x} and always return a “classed” Matrix.

Applied to a \texttt{\textit{matrix}} object \texttt{m}, \texttt{M \leftarrow Matrix(m)} can be considered a kind of inverse of \texttt{m \leftarrow as(M, \texttt{"matrix"})}. For sparse matrices however, \texttt{M} well be a \texttt{CsparseMatrix}, and it is often “more structured” than \texttt{M}, e.g.,
Rule 3: All the following coercions to virtual matrix classes should work:

1. as(m, "dMatrix")
2. as(m, "lMatrix")
3. as(m, "nMatrix")
4. as(m, "denseMatrix")
5. as(m, "sparseMatrix")
6. as(m, "generalMatrix")

whereas the next ones should work under some assumptions:

1. as(m1, "triangularMatrix")
   should work when m1 is a triangular matrix, i.e. the upper or lower triangle of m1 contains only zeros.
2. as(m2, "symmetricMatrix") should work when m2 is a symmetric matrix in the sense of isSymmetric(m2) returning TRUE. Note that this is typically equivalent to something like isTRUE(all.equal(m2, t(m2))), i.e., the lower and upper triangle of the matrix have to be equal up to small numeric fuzz.

3 Session Info

> toLatex(sessionInfo())

- R version 3.5.1 Patched (2018-10-19 r75465), x86_64-pc-linux-gnu
• Locale: LC_CTYPE=de_CH.UTF-8, LC_NUMERIC=C, LC_TIME=en_US.UTF-8, LC_COLLATE=C, LC_MONETARY=en_US.UTF-8, LC_MESSAGES=de_CH.UTF-8, LC_PAPER=de_CH.UTF-8, LC_NAME=C, LC_ADDRESS=C, LC_TELEPHONE=C, LC_MEASUREMENT=de_CH.UTF-8, LC_IDENTIFICATION=C

• Running under: Fedora 28 (Twenty Eight)

• Matrix products: default

• BLAS:
  /sfs/u/maechler/R/D/r-patched/F28-64-inst/lib/libRblas.so

• LAPACK:
  /sfs/u/maechler/R/D/r-patched/F28-64-inst/lib/libRlapack.so

• Base packages: base, datasets, grDevices, graphics, methods, stats, utils

• Other packages: Matrix 1.2-15

• Loaded via a namespace (and not attached): compiler 3.5.1, grid 3.5.1, lattice 0.20-35, tools 3.5.1
