Sample estimation of reliability of stress-strength models

Description

The function provides sample estimates of reliability of stress-strength models, where stress and strength are modeled as independent r.v., whose distribution form is known except for the values of its parameters, assumed all unknown
Usage

estSSR(x, y, family="normal", twoside=TRUE, type="RG", alpha=0.05, B=2000)

Arguments

x a random sample from r.v. X modeling strength
y a random sample from r.v. Y modeling stress
family the distribution of both X and Y
twoside if TRUE, the function computes two-side confidence intervals; otherwise, one-side (a lower bound)
type type of confidence interval (CI) to be built. For the normal family, "RG" stands for Reiser-Guttman, "AN" for large sample (asymptotically normal), "LOGIT" or "ARCSIN" for logit or arcsin variance stabilizing tranformations, "B" for percentile bootstrap, "GK" for Guo-Krishnamoorthy (one-sided only).
alpha the complement to one of the nominal confidence level
B number of bootstrap replicates (for type "B")

Details

For more details, please have a look at the references listed below

Value

A list comprising

ML_est the sample value of the maximum likelihood estimator; for normal r.v. \( \hat{R} = \Phi(\bar{x} - \bar{y})/\sqrt{\hat{\sigma}_x^2 + \hat{\sigma}_y^2} \), where \( \bar{x} \) and \( \bar{y} \) are the sample means, and \( \hat{\sigma}_x^2, \hat{\sigma}_y^2 \) the biased maximum likelihood variance estimators
Downton_est (for normal r.v.) the sample value of one of the approximated UMVU estimators proposed by Downton \( \hat{R}' = \Phi(\bar{x} - \bar{y})/\sqrt{s_x^2 + s_y^2} \)
CI the confidence interval
certainty_level the nominal confidence level \( 1 - \alpha \)

estSSR(x, y, type="B")
gkf

Description

It provides the solution of the equation \( F_t(q; df, x) = p \), where \( F_t \) is the cdf (calculated in \( q \)) of a non-central Student r.v. with \( df \) degrees of freedom and unknown noncentrality parameter \( x \). In R code, gkf provides the solution of \( pt(q, df, x) = p \).

Usage

```
gkf(p, q, df, eps = 1e-05)
```

Arguments

- \( p \) a probability
- \( q \) a real value
- \( df \) degrees of freedom of noncentral T
- \( eps \) tolerance

Details

This function is used for building Guo-Krishnamoorthy confidence intervals for R

Value

the noncentrality parameter \( x \) satisfying the equation \( F_t(q; df, x) = p \)

**SSR**

*Computation of reliability of stress-strength models*

**Description**

For a stress-strength model, with independent r.v. $X$ and $Y$ representing the strength and the stress respectively, the function computes the reliability $R = P(X > Y)$.

**Usage**

```r
SSR(parx, pary, family = "normal")
```

**Arguments**

- `parx`: parameters of $X$ distribution (for the normal distribution, mean $\mu_x$ and standard deviation $\sigma_x$)
- `pary`: parameters of $Y$ distribution (for the normal distribution, mean $\mu_y$ and standard deviation $\sigma_y$)
- `family`: family distribution for both $X$ and $Y$ (now, only "normal" available)

**Details**

The function computes $R = P(X > Y)$ where $X$ and $Y$ are independent r.v. following the *family* distribution with distributional parameters `parx` and `pary`.

**Value**

$R = P(X > Y)$. For normal distributions, $R = \Phi(d)$ with $d = (\mu_x - \mu_y)/\sqrt{\sigma_x^2 + \sigma_y^2}$.
