inspectDT  

**Inspect Associations Interactively Using datatable**

**Description**

Uses `datatable` to create a HTML table widget using the DataTables library. Rules can be interactively filtered and sorted.

**Usage**

```r
inspectDT(x, ...)```

**Arguments**

- `x` an object of class "rules" or "itemsets".
- `...` additional arguments. `precision` controls the precision used to print the quality measures (defaults to 2). All other arguments are passed on to `datatable`.

**Value**

A datatable htmlwidget.

**Author(s)**

Michael Hahsler

**See Also**

`datatable` in `DT`.

**Examples**

```r
## Not run:
data(Groceries)
rules <- apriori(Groceries, parameter=list(support=0.005, confidence=0.5))
rules

inspectDT(rules)

### save table as a html page.
p <- inspectDT(rules)
htmlwidgets::saveWidget(p, "arules.html", selfcontained = FALSE)
browseURL("arules.html")
## End(Not run)```
Description

Methods (S3) to visualize association rules and itemsets. Implemented are several popular visualization methods including scatter plots with shading (two-key plots), graph based visualizations, doubledecker plots, etc.

Many plots can use different rendering engines including static standard plots (mostly using `grid`), standard plots with interactive manipulation and interactive HTML widget-based visualizations.

Usage

```r
## S3 method for class 'rules'
plot(x, method = NULL, measure = "support", shading = "lift",
     interactive = NULL, engine = "default", data = NULL, control = NULL, ...)
## S3 method for class 'itemsets'
plot(x, method = NULL, measure = "support", shading = NA,
     interactive = NULL, engine = "default", data = NULL, control = NULL, ...)
```

Arguments

- `x` an object of class "rules" or "itemsets".
- `method` a string with value "scatterplot", "two-key plot", "matrix", "matrix3D", "mosaic", "doubledecker", "graph", "paracoord" or "grouped", "iplots" selecting the visualization method (see Details).
- `measure` measure(s) of interestingness (e.g., "support", "confidence", "lift", "order") used in the visualization. Some visualization methods need one measure, others take a vector with two measures (e.g., scatterplot). In some plots (e.g., graphs) `NA` can be used to suppress using a measure.
- `shading` measure of interestingness used for the color of the points/arrows/nodes (e.g., "support", "confidence", "lift"). The default is "lift". `NA` can be often used to suppress shading.
- `interactive` deprecated. See parameter `engine` below.
- `control` a list of control parameters for the plot. The available control parameters depend on the used visualization method (see Details).
- `data` the dataset (class "transactions") used to generate the rules/itemsets. Only "mosaic" and "doubledecker" require the original data.
- `engine` a string indicating the plotting engine used to render the plot. The "default" engine uses (mostly) `grid`, but some plots can produce interactive grid visualizations using engine "interactive", or HTML widgets using engine "htmlwidget". These widgets can be saved as stand-alone web pages (see Examples). Note that HTML widgets tend to get very slow or unresponsive for too many rules. To prevent this situation, the control parameter `max` sets a limit, and the user is warned if the limit is reached.
- `...` Further arguments are added for convenience to the `control` list.
Details

Most visualization techniques are described by Bruzzese and Davino (2008), however, we added more color shading, reordering and interactive features. Many visualization methods take extra parameters as the control parameter list. Although, we have tried to keep control parameters consistent, the available control parameters vary (slightly) from visualization method to visualization method. A complete list of parameters with default values can be obtained using verbose mode. For example,

```
plot(rules, method = "graph", control = list(verbos = TRUE))
```

prints a complete list of control parameters for method "graph" (default engine).

The following visualization method are available:

"scatterplot", "two-key plot" This visualization method draws a two dimensional scatterplot with different measures of interestingness (parameter "measure") on the axes and a third measure (parameter "shading") is represented by the color of the points. There is a special value for shading called "order" which produces a two-key plot where the color of the points represents the length (order) of the rule.

Interactive manipulations are available. Engine "htmlwidget" is available to produce an interactive web-based visualization (uses plotly).

"matrix" Arranges the association rules as a matrix with the itemsets in the antecedents on one axis and the itemsets in the consequents on the other. The measure of interestingness (first element of measure) is either visualized by a color (darker means a higher value for the measure) or as the height of a bar (engine "3d"). Interactive visualizations using engine "interactive" or "htmlwidget" (via plotly) are available.

"grouped matrix" Grouped matrix-based visualization (Hahsler and Karpienko, 2016; Hahsler 2016). Antecedents (columns) in the matrix are grouped using clustering. Groups are represented by the most interesting item (highest ratio of support in the group to support in all rules) in the group. Balloons in the matrix are used to represent with what consequent the antecedents are connected.

Interactive manipulations (zooming into groups and identifying rules) are available.

The list of control parameters for this method includes:

"main" plot title
"k" number of antecedent groups (default: 20)
"rhs_max" maximal number of RHSs to show. The rest are suppressed. (default: 10)
"lhs_items" number of LHS items shown (default: 2)
"aggr.fun" aggregation function can be any function computing a scalar from a vector (e.g., min, mean (default), median, sum, max). It is also used to reorder the balloons in the plot.
"col" color palette (default is 100 heat colors.)
"gp_labels", "gp_main", "gp_labs", "gp_lines" gpar() objects used to specify color, font and font size for different elements.

"graph" Represents the rules (or itemsets) as a graph with items, itemsets, and rules represented as vertices.

Several engines are available. The default engine uses igraph (plot.igraph and tkplot for the interactive visualization). . . . arguments are passed on to the respective plotting function (use for color, etc.).
Alternatively, the engines "graphviz" (Rgraphviz) and "htmlwidget" (visNetwork) are available. Note that Rgraphviz has to be installed separately from http://www.bioconductor.org/.

"doubledecker", "mosaic" Represents a single rule as a doubledecker or mosaic plot. Parameter data has to be specified to compute the needed contingency table. No interactive version is available.

"paracoord" Represents the rules (or itemsets) as a parallel coordinate plot. Currently there is no interactive version available.

"iplots" Experimental interactive plots (package iplots) which support selection, highlighting, brushing, etc. Currently plots a scatterplot (support vs. confidence) and several histograms. Interactive manipulations are available.

Value

Several interactive plots return a set of selected rules/itemsets. Other plots might return other data structures. For example, graph-based plots return the graph (invisibly). Engine "htmlwidget" always returns an object of class htmlwidget.

Author(s)

Michael Hahsler and Sudheer Chelluboina. Some visualizations are based on the implementation by Martin Vodenicharov.

p <- plotly_arules(rules)
htmlwidgets::saveWidget(p, "arules.html", selfcontained = FALSE)
browseURL("arules.html")
```

```
# Note: selfcontained seems to make the browser slow.
```

### plotly_arules

**Interactive Scatter Plot for Association Rules using plotly**

#### Description

Plot an interactive scatter plot for association rules using `plotly`.

#### Usage

```r
plotly_arules(x, method = "scatterplot", measure = c("support", "confidence"), shading = "lift", max = 1000, ...)
```

#### Arguments

- **x**: An object of class "rules".
- **method**: Currently, the methods "scatterplot", "two-key plot" and "matrix" are supported.
- **measure**: Measure(s) of interestingness (e.g., "support", "confidence", "lift", "order") used in the visualization as x and y-axis.
- **shading**: Measure of interestingness used for color shading.
- **max**: Client side processing in plotly is expensive. We restrict the number of rules to the max best rules (according to the measure used for shading.)
saveAsGraph

The following additional arguments can be used: `colors` to specify a color palette, `precision` to specify the precision used for printing quality measures, `jitter` to reduce overplotting in scatterplots (defaults to .1 if overplotting would occur), and `marker` with a list of marker attributes (e.g., size, symbol and opacity).

Value

The plotly object (plotly_hash) which can be saved as a htmlwidget.

Examples

```r
## Not run:
library(plotly)
data(Groceries)
rules <- apriori(Groceries, parameter=list(support=0.001, confidence=0.8))
rules

# interactive scatter plot visualization
plotly_arules(rules)
plotly_arules(rules, measure = c("support", "lift"), shading = "confidence")
plotly_arules(rules, method = "two-key plot")

# add jitter, change color and markers and add a title
plotly_arules(rules, jitter = 10,
marker = list(opacity = .7, size = 10, symbol = 1),
colors = c("blue", "green"))

# save a plot as a html page
p <- plotly_arules(rules)
htmlwidgets::saveWidget(p, "arules.html", selfcontained = FALSE)
browseURL("arules.html")
# Note: selfcontained seems to make the browser slow.

# interactive matrix visualization
plotly_arules(rules, method = "matrix")

## End(Not run)
```

Description

This function saves a rule set as a graph description in different formats (e.g., GraphML, dimacs, dot).
saveAsGraph

Usage

saveAsGraph(x, file, type="items", format="graphml")

Arguments

- x: an object of class "rules" or "itemsets".
- file: file name
- type: see type in plot with method "graph" (e.g., "itemsets", "items").
- format: file format (e.g., "edgelist", "graphml", "dimacs", "gml", "dot"). See write.graph in package igraph.
