Package ‘httpuv’

July 4, 2017

Type Package
Title HTTP and WebSocket Server Library
Version 1.3.5
Author Joe Cheng, Hector Corrada Bravo [ctb], Jeroen Ooms [ctb], Winston Chang [ctb]
Copyright RStudio, Inc.; Joyent, Inc.; Nginx Inc.; Igor Sysoev; Niels Provos; Internet Systems Consortium, Inc.; Alexander Chemeris
Maintainer Joe Cheng <joe@rstudio.com>
Description Provides low-level socket and protocol support for handling HTTP and WebSocket requests directly from within R. It is primarily intended as a building block for other packages, rather than making it particularly easy to create complete web applications using httpuv alone. httpuv is built on top of the libuv and http-parser C libraries, both of which were developed by Joyent, Inc. (See LICENSE file for libuv and http-parser license information.)

Description

HTTP and WebSocket server

Details

Allows R code to listen for and interact with HTTP and WebSocket clients, so you can serve web traffic directly out of your R process. Implementation is based on libuv and http-parser.

This is a low-level library that provides little more than network I/O and implementations of the HTTP and WebSocket protocols. For an easy way to create web applications, try Shiny instead.

Author(s)

Joe Cheng <joe@rstudio.com>

See Also

startServer

Examples

## Not run:
demo("echo", package="httpuv")

## End(Not run)
**Description**

Encodes/decodes strings using URI encoding/decoding in the same way that web browsers do. The precise behaviors of these functions can be found at developer.mozilla.org: `encodeURI, encodeURIComponent, decodeURI, decodeURIComponent`

**Usage**

`encodeURI(value)`

`encodeURIComponent(value)`

`decodeURI(value)`

`decodeURIComponent(value)`

**Arguments**

`value` Character vector to be encoded or decoded.

**Details**

Intended as a faster replacement for `urlencode` and `urldecode`.

`encodeURI` differs from `encodeURIComponent` in that the former will not encode reserved characters: `;,:/?@&=+$`

`decodeURI` differs from `decodeURIComponent` in that it will refuse to decode encoded sequences that decode to a reserved character. (If in doubt, use `decodeURIComponent`.)

The only way these functions differ from web browsers is in the encoding of non-ASCII characters. All non-ASCII characters will be escaped byte-by-byte. If conformant non-ASCII behavior is important, ensure that your input vector is UTF-8 encoded before calling `encodeURI` or `encodeURIComponent`.

**Value**

Encoded or decoded character vector of the same length as the input value.
interrupt  \hspace{1cm} \textit{Interrupt httpuv runloop}

\textbf{Description}

Interrupts the currently running httpuv runloop, meaning \texttt{runServer} or \texttt{service} will return control back to the caller and no further tasks will be processed until those methods are called again. Note that this may cause in-process uploads or downloads to be interrupted in mid-request.

\textbf{Usage}

\begin{verbatim}
interrupt()
\end{verbatim}

\textbf{rawToBase64}  \hspace{1cm} \textit{Convert raw vector to Base64-encoded string}

\textbf{Description}

Converts a raw vector to its Base64 encoding as a single-element character vector.

\textbf{Usage}

\begin{verbatim}
rawToBase64(x)
\end{verbatim}

\textbf{Arguments}

\begin{verbatim}
\textbf{x} \hspace{0.5cm} A raw vector.
\end{verbatim}

\textbf{Examples}

\begin{verbatim}
set.seed(100)
result <- rawToBase64(as.raw(runif(19, min=0, max=256)))
stopifnot(identical(result, "TkGNDmd7z16LK5/hR2b0qaRbXA="))
\end{verbatim}
runServer

---

### Description

This is a convenience function that provides a simple way to call `startServer`, `service`, and `stopServer` in the correct sequence. It does not return unless interrupted or an error occurs.

### Usage

```plaintext
runServer(host, port, app, interruptIntervalMs = ifelse(interactive(), 100, 1000))
```

### Arguments

- **host**: A string that is a valid IPv4 address that is owned by this server, or "0.0.0.0" to listen on all IP addresses.
- **port**: A number or integer that indicates the server port that should be listened on. Note that on most Unix-like systems including Linux and Mac OS X, port numbers smaller than 1025 require root privileges.
- **app**: A collection of functions that define your application. See `startServer`.
- **interruptIntervalMs**: How often to check for interrupt. The default should be appropriate for most situations.

### Details

If you have multiple hosts and/or ports to listen on, call the individual functions instead of `runServer`.

### See Also

- `startServer`, `service`, `stopServer`

---

service

---

### Description

Process HTTP requests and WebSocket messages. Even if a server exists, no requests are serviced unless and until `service` is called.

### Usage

```plaintext
service(timeoutMs = ifelse(interactive(), 100, 1000))
```
Arguments

timeoutMs  Approximate number of milliseconds to run before returning. If 0, then the function will continually process requests without returning unless an error occurs. If NA, performs a non-blocking run without waiting.

Details

Note that while service is waiting for a new request, the process is not interruptible using normal R means (Esc, Ctrl+C, etc.). If being interruptible is a requirement, then call service in a while loop with a very short but non-zero `Sys.sleep` during each iteration.

Examples

```r
## Not run:
while (TRUE) {
  service()
  Sys.sleep(0.001)
}
## End(Not run)
```

---

`startDaemonizedServer`  
*Create an HTTP/WebSocket daemonized server (experimental)*

Description

Creates an HTTP/WebSocket server on the specified host and port. The server is daemonized so R interactive sessions are not blocked to handle requests.

Usage

`startDaemonizedServer(host, port, app)`

Arguments

- **host**  A string that is a valid IPv4 address that is owned by this server, or "0.0.0.0" to listen on all IP addresses.
- **port**  A number or integer that indicates the server port that should be listened on. Note that on most Unix-like systems including Linux and Mac OS X, port numbers smaller than 1025 require root privileges.
- **app**  A collection of functions that define your application. See Details.
startServer

Details

In contrast to servers created by `startServer`, calls to `service` are not needed to accept and handle connections. If the port cannot be bound (most likely due to permissions or because it is already bound), an error is raised.

The `app` parameter is where your application logic will be provided to the server. This can be a list, environment, or reference class that contains the following named functions/methods:

- `call(req)`: Process the given HTTP request, and return an HTTP response. This method should be implemented in accordance with the Rook specification.
- `onHeaders(req)`: Optional. Similar to `call`, but occurs when headers are received. Return NULL to continue normal processing of the request, or a Rook response to send that response, stop processing the request, and ask the client to close the connection. (This can be used to implement upload size limits, for example.)
- `onWSOpen(ws)`: Called back when a WebSocket connection is established. The given object can be used to be notified when a message is received from the client, to send messages to the client, etc. See WebSocket.

The `startPipeServer` variant is not supported yet.

Value

A handle for this server that can be passed to `stopDaemonizedServer` to shut the server down.

See Also

- `startServer`
## Arguments

- **host**: A string that is a valid IPv4 address that is owned by this server, or "0.0.0.0" to listen on all IP addresses.
- **port**: A number or integer that indicates the server port that should be listened on. Note that on most Unix-like systems including Linux and Mac OS X, port numbers smaller than 1024 require root privileges.
- **app**: A collection of functions that define your application. See Details.
- **name**: A string that indicates the path for the domain socket (on Unix-like systems) or the name of the named pipe (on Windows).
- **mask**: If non-NULL and non-negative, this numeric value is used to temporarily modify the process's umask while the domain socket is being created. To ensure that only root can access the domain socket, use `strtol("777", 8)`; or to allow owner and group read/write access, use `strtol("666", 8)`. If the value is NULL then the process's umask is left unchanged. (This parameter has no effect on Windows.)

## Details

`startServer` binds the specified port, but no connections are actually accepted. See `service`, which should be called repeatedly in order to actually accept and handle connections. If the port cannot be bound (most likely due to permissions or because it is already bound), an error is raised.

The app parameter is where your application logic will be provided to the server. This can be a list, environment, or reference class that contains the following named functions/methods:

- `call(req)`: Process the given HTTP request, and return an HTTP response. This method should be implemented in accordance with the Rook specification.
- `onHeaders(req)`: Optional. Similar to `call`, but occurs when headers are received. Return NULL to continue normal processing of the request, or a Rook response to send that response, stop processing the request, and ask the client to close the connection. (This can be used to implement upload size limits, for example.)
- `onWSOpen(ws)`: Called back when a WebSocket connection is established. The given object can be used to be notified when a message is received from the client, to send messages to the client, etc. See `WebSocket`.

The `startPipeServer` variant can be used instead of `startServer` to listen on a Unix domain socket or named pipe rather than a TCP socket (this is not common).

## Value

A handle for this server that can be passed to `stopServer` to shut the server down.

## See Also

`runServer`
**stopDaemonizedServer**  
*Stop a running daemonized server in Unix environments*

**Description**
Given a handle that was returned from a previous invocation of `startDaemonizedServer`, closes all open connections for that server, removes listeners in the R event loop and unbinds the port. **Be careful not to call `stopDaemonizedServer` more than once on a handle, as this will cause the R process to crash!**

**Usage**
```r
stopDaemonizedServer(server)
```

**Arguments**
- `server` A handle that was previously returned from `startDaemonizedServer`.

**stopServer**  
*Stop a running server*

**Description**
Given a handle that was returned from a previous invocation of `startServer`, closes all open connections for that server and unbinds the port. **Be careful not to call `stopServer` more than once on a handle, as this will cause the R process to crash!**

**Usage**
```r
stopServer(handle)
```

**Arguments**
- `handle` A handle that was previously returned from `startServer`. 
**Description**

An object that represents a single WebSocket connection. The object can be used to send messages and close the connection, and to receive notifications when messages are received or the connection is closed.

**Arguments**

... For internal use only.

**Details**

WebSocket objects should never be created directly. They are obtained by passing an onWSOpen function to `startServer`.

**Fields**

- request: The Rook request environment that opened the connection. This can be used to inspect HTTP headers, for example.

**Methods**

- onMessage(func): Registers a callback function that will be invoked whenever a message is received on this connection. The callback function will be invoked with two arguments. The first argument is `TRUE` if the message is binary and `FALSE` if it is text. The second argument is either a raw vector (if the message is binary) or a character vector.

- onClose(func): Registers a callback function that will be invoked when the connection is closed.

- send(message): Begins sending the given message over the websocket. The message must be either a raw vector, or a single-element character vector that is encoded in UTF-8.

- close(): Closes the websocket connection.
