Description

This package provides functionality for automatic interpolation of spatial data. The package was originally developed as the computational back-end of the intamap web service, but is now a stand-alone package as maintenance of the web service has ended.

General setup

The normal work flow for working with the intamap package can best be illustrated with the following R-script. The procedure starts with reading data and meta data, then setting up an object which is used in the following functions: preprocess data, estimate parameters, compute spatial predictions, and post process them (i.e., write them out):

```r
library(intamap)

# set up intamap object, either manually:
obj = list(
  observations = readOGR("PG:dbname=postgis", "eurdep.data"),
  predictionLocations = readOGR("PG:dbname=postgis", "eurdep1km.grid"),
  targetCRS = "+init=epsg:3035",
  params = getIntamapParams()
)
```
class(obj) = c("idw")

# or using createIntamapObject
obj = createIntamapObject(
    observations = readOGR("PG:dbname=postgis", "eurdep.data"),
    predictionLocations = readOGR("PG:dbname=postgis", "eurdep1km.grid"),
    targetCRS = "+init=epsg:3035", class = c("idw")
)

# run test:
checkSetup(obj)

# do interpolation steps:
obj = preProcess(obj)
obj = estimateParameters(obj)  # faster
obj = spatialPredict(obj)
obj = postProcess(obj)

Our idea is that a script following this setup will allow the full statistical analysis required for the R
back-end to the automatic interpolation service, and provides the means to extend the current (over-
simplistic) code with the full-grown statistical analysis routines developed by INTAMAP partners.
Running the package independently under R gives the user more flexibility in the utilization than
what is possible through the web-interface.
Let us look into detail what the code parts do:

library(intamap)

The command library(intamap) loads the R code of the intamap package to the current R ses-
sion, along with the packages required for this (sp, gstat, akima, automap, mvtnorm, evd, MASS).
It is also recommended to install and load rgdal on those platforms where this package is available.
All packages need to be available to the R session, which is possible after downloading them from
the Comprehensive R Network Archives (CRAN) (https://cran.r-project.org)

# set up intamap object:
obj = createIntamapObject(
    observations = readOGR("PG:dbname=postgis", "eurdep.data"),
    predictionLocations = readOGR("PG:dbname=postgis", "inspire1km.grid"),
    targetCRS = "+init=epsg:3035",
    class = "idw"
)

This code sets up a list object called obj, and assigns a class (or a group of classes) to it. This
list should hold anything we need in the next steps, and the bare minimum seems to be measured
point data (which will be extended to polygon data) and prediction locations, and a suggestion what
to do with it. Here, the data are read from a PostGIS data base running on localhost; data base
connections over a network are equally simple to set up. From the data base postgis the tables eurdep.data and inspire1km.grid are read; it is assumed that these have their SRID (spatial reference identifier) set.

The suggestion what to do with these data is put in the classes, idw. This will determine which versions of preprocess, parameterEstimate etc will be used: intamap provides methods for each of the generic functions preprocess, estimateParameters, spatialPredict, postProcess. Although it would be possible to apply two classes in this case (dataType in addition to idw), as the choice of pre- and post-processing steps tend to be data-dependent, we have tried to limit the number of classes to one for most applications.

The S3 method mechanism (used here) hence requires these versions to be called preprocess.idw, estimateParameters.idw, spatialPredict.idw, and postProcess.idw (and eventually also preprocess.eurdep and preprocess.eurdep).

To see that, we get in an interactive session:

```r
> library(intamap)
Loading required package: sp
Loading required package: gstat
Loading required package: rgdal
Geospatial Data Abstraction Library extensions to R successfully loaded
> methods(estimateParameters)
 [1] estimateParameters.automap* estimateParameters.copula*
 [3] estimateParameters.default* estimateParameters.idw*
 [5] estimateParameters.linearVariogram* estimateParameters.transGaussian*
 [7] estimateParameters.yamamoto*
```

Now if a partner provides additional methods for BayesianKriging, one could integrate them by

```r
class(obj) = "BayesianKriging"
```

and provide some or all of the functions preprocess.BayesianKriging.estimateParameters.BayesianKriging, spatialPredict.BayesianKriging, and postProcess.BayesianKriging, which would be called automatically when using their generic form (preProcess etc).

It is also possible to provide a method that calls another method. Further, for each generic there is a default method. For estimateParameter and spatialPredict these print an error message and stop, for the pre- and postprocessing the default methods may be the only thing needed for the full procedure; if no preprocess.BayesianKriging is found, preprocess.default will be used when the generic (preProcess) is called.

If a method does something, then it adds its result to the object it received, and returns this object. If it doesn’t do anything, then it just passes (returns) the object it received.

To make these different methods exchangable, it is needed that they can all make the same assumptions about the contents of the object that they receive when called, and that what they return complies with what the consequent procedures expect. The details about that are given in the descriptions of the respective methods, below.

Because a specific interpolation method implemented may have its peculiar characteristics, it may have to extend these prescriptions by passing more information than described below, for example information about priors from estimateParameters to spatialPredict.
The choice between methods is usually done based on the type of problem (extreme values present, computation time available etc.). The possibility for parallel processing of the prediction step is enabled for some of the main methods. To be able to take advantage of multiple CPUs on a computer, the package doParallel must be installed, additionally the parameter nclus must be set to a value larger than 1.

Input object components

- **observations** object of class \code{SpatialPointsDataFrame}, containing a field value that is the target variable.
- **predictionLocations** object extending class \code{Spatial}, containing prediction locations.
- **targetcrs** character; target CRS or missing
- **formulaString** formula string for parameter estimation and prediction functions
- **params** list of parameters, to be set in \code{getIntamapParams}. These parameters include:
  - \code{doAnisotropy = FALSE} Defining whether anisotropy should be calculated
  - \code{removeBias = NA} Defining whether biases should be removed, and in case yes, which ones (localBias and regionalBias implemented)
  - \code{addBias = NA} Defining which biases to be added in the \code{postProcess} function. This has not yet been implemented.
  - \code{biasRemovalMethod = "LM"} character; specifies which methods to use to remove bias. See below.
  - \code{doSegmentation = FALSE} Defining if the predictions should be subject to segmentation. Segmentation has been implemented, but not the use of it.
  - \code{nmax = 50} for local kriging: the number of nearest observations that should be used for a kriging prediction or simulation, where nearest is defined in terms of the space of the spatial locations. By default, 50 observations are used.
  - \code{ngrid = 100} The number of grid points to be used if an Averaged Cumulative Distribution Function (ACDF) needs to be computed for unbiased kriging
  - \code{nsim=100} Number of simulations when needed
  - \code{block = numeric(0)} Block size; a vector with 1, 2 or 3 values containing the size of a rectangular in x-, y- and z-dimension respectively (0 if not set), or a data frame with 1, 2 or 3 columns, containing the points that discretize the block in the x-, y- and z-dimension to define irregular blocks relative to (0,0) or (0,0,0) - see also the details section of \code{predict.gstat}. By default, predictions or simulations refer to the support of the data values.
  - \code{processType = "gaussian"} If known - the distribution of the data. Defaults to gaussian, analytical solutions also exists in some cases for logNormal. This setting only affects a limited number of methods, e.g. the block predicton
  - \code{confProj = FALSE} If set, the program will attempt conform projections in \code{preProcess}, calling the function \code{conformProjections}.
  - \code{nclus = 1} The number of clusters to use, if applying to a method which can run processes in parallel. Currently implemented for methods automap, copula and psgp.
  - \code{debug.level = 0} Used in some functions for giving additional output. See individual functions for more information.

... Additional parameters that do not exist in the default parameter set, particularly parameters necessary for new methods within the `intamap` package
bayesCopula

**Description**

Calculates predictive mean, predictive variance, predictive quantiles and exceedance probabilities for certain thresholds in the spatial copula model.

**Usage**

```r
bayesCopula(obj, estimates, search=10, calc=list(mean=TRUE, variance=TRUE), testMean=FALSE)
```

**Arguments**

- `obj` Intamap object including observations and predictionLocations, see `intamap-package`
- `estimates` List of estimated parameters (typically obtained by calling `copulaEstimation`)
- `search` local prediction: number of observed locations considered for prediction at each unknown point
- `calc` list of what prediction type is required:
  - `mean` = TRUE if the predictive mean should be calculated, FALSE otherwise
  - `variance` = TRUE if the predictive variance should be calculated, FALSE otherwise
  - `quantiles` = NULL Vector of desired predictive quantiles, e.g. 0.95 or 0.05
  - `excprob` = NULL Vector of thresholds, where the probability of exceeding this threshold is desired
- `testMean` Whether or not the predictive means (if calculated) should be tested for being reasonable.

**Details**

bayesCopula is used for plug-in prediction at unobserved spatial locations. The name of the function is somewhat misleading since no Bayesian approach is implemented so far. It is possible to calculate numerically the predictive mean and variance for both the Gaussian and the chi-square spatial copula model. Exceedance probabilities and predictive quantiles are only supported for the Gaussian copula model. Note that it may occur that the predictive distribution has no finite moments. In this case, a possible predictor is the median of the predictive distribution. If testMean=TRUE and the predictive means have no reasonable values, the median is automatically calculated and a warning is produced.

The copula prediction method is computationally demanding. There is a possibility of running it as a parallel process by setting the parameter `nclus > 1` for the interpolation process. This requires a previous installation of the package `doParallel`.

**References**

bayesCopula

Value

List with the following elements:

mean Mean of the predictive distribution. NULL if not calculated.

variance Variance of the predictive distribution. NULL if not calculated.

quantiles Quantiles of the predictive distribution NULL if not calculated.

excprob Probabilities for the predictive distribution to exceed predefined thresholds. NULL if not calculated.

    calc = list(mean = TRUE, variance = TRUE, excprob = 40, quantile = 0.95))

## End(Not run)
**blockPredict**  

*Spatial block prediction*

**Description**

`blockPredict` is a generic method for prediction of spatially aggregated variables within the `intamap-package` package.

**Usage**

```
blockPredict(object, ...)  
```

**Arguments**

- **object**
  - a list object of the type described in `intamap-package`
- ...  
  - other arguments that will be passed to the requested interpolation method. See the individual interpolation methods for more information. The following arguments from `object` can be overruled through `...`:
  - **block**  
    - Block size: a vector with 1, 2 or 3 values containing the size of a rectangular in x-, y- and z-dimension respectively (0 if not set), or a data frame with 1, 2 or 3 columns, containing the points that discretize the block in the x-, y- and z-dimension to define irregular blocks relative to (0,0) or (0,0,0) - see also the details section of `predict.gstat`. By default, predictions or simulations refer to the support of the data values.
  - **cellsize**  
    - size of cells for discretization of blocks for numerical simulation

**Details**

The function `blockPredict` is a wrapper around the `spatialPredict.block` function within the `intamap-package` package, to simplify the calls for block predictions.

Block predictions are spatial predictions assumed to be valid for a certain area. The blocks can either be given by passing `SpatialPolygons` as the predictionLocations or by passing the block-argument through the parameters of the object or through the `...`-argument.

There are essentially two ways to solve the problems of block predictions.

- **analytical** block predictions can be found directly by block kriging
- **numerical** block predictions can be found through numerical simulations over a set of points within the block, the requested output is found by averaging over these simulations

The analytical solutions are used when applicable. This is typically for ordinary kriging based methods and prediction types that can be found by linear aggregation (e.g. block mean).

If the prediction type necessitates simulations, this is done by subsampling the blocks. This can either be done block-wise, with a certain number of points within each block, with a certain `cellsize`, or with a certain number of points.

`automap` uses function `autoKrig` in the `automap` package. If `object` already includes a variogram model, `krig` in the `gstat-package` will be called directly.
Value

A list object similar to object, but extended with predictions at a set of locations defined object.

Examples

# This example skips some steps that might be necessary for more complicated tasks, such as estimateParameters and pre- and postProcessing of the data

data(meuse)
coordinates(meuse) = ~x+y
meuse$value = log(meuse$zinc)
data(meuse.grid)
grid(meuse.grid) = ~x+y
proj4string(meuse) = CRS("+init=epsg:28992")
proj4string(meuse.grid) = CRS("+init=epsg:28992")

# set up intamap object:
obj = createIntamapObject(
  observations = meuse,
predictionLocations = meuse.grid[sample(1:length(meuse.grid),10),],
# Prediction for a different projection possible if rgdal is available
targetCRS = ifelse(require(rgdal), "+init=epsg:3035", "+init=epsg:28992"),
class = "automap"
)

# do interpolation step:
obj = conformProjections(obj)
obj = estimateParameters(obj)
obj = blockPredict(obj, block=c(100,100))  # blockPredict

# intamap object for which simulation is needed:
meuse$value = meuse$zinc
obj = createIntamapObject(
  observations = meuse,
predictionLocations = meuse.grid[sample(1:length(meuse.grid),5),],
params = list(ngrid = 16),
class = "transGaussian"  # trans-Gaussian kriging method
)
checkSetup

Description
checkSetup will do some sanity checks on input data provided through object.

Usage
checkSetup(object, quiet = FALSE)

Arguments
object object, to be passed to preProcess, see intamap-package
quiet logical; TRUE to suppress OK statement

Details
checkSetup is a function that makes certain tests on the intamap object to make sure that it is suited for interpolation. Particularly, it will issue a warning or an error if one of the following conditions are met:

- observations is not an element of object
- observations contain less than 20 observations
- Some of the observation locations are duplicated
- formulaString is not an element of object
- None of the columns of observations has a name that corresponds to the independent variable of formulaString
- predictionLocations is not an element of object
- predictionLocations is not a Spatial object
- targetCRS is given, but observations and predictionLocations do not have CRS set
- addBias includes biases that are not part of removeBias

The function will issue a warning if it appears that predictionLocations and observations share a small region. This warning is given as it is a likely cause of errors, although it can also happen if predictionLocations are limited to one small cluster.

Value
returns TRUE if check passes, will halt with error when some error condition is met.

Edzer J. Pebesma
coarsenGrid

coarsenGrid is a function that resamples a SpatialGridDataFrame.

Usage

coarsenGrid(object, coarse = 2, offset = sample(c(0:(coarse - 1)), 2, replace = TRUE))

Arguments

object       a SpatialGridDataFrame or gridded SpatialPixelsDataFrame
coarse       an integer telling how much the grid should be coarsened
offset       integer giving the relative offset of the first point, see details below for a closer description

Details

The function `coarsenGrid` is a function that samples from a SpatialGridDataFrame. The argument `coarse` indicates that every `coarse` row and column will be sampled, starting with the row and column represented in `offset`. `offset = c(0,0)` implies that the smallest x- and y-coordinates will be a part of the resampled data set, `offset = c(1,1)` implies that sampling will start on the second row and column.

Value

a SpatialGridDataFrame.

Author(s)

Jon Olav Skoien

References

conformProjections

Description

Getting a conformed projection for a set of Spatial* elements necessary for interpolation in the intamap-package.

Usage

conformProjections(object)

Arguments

object an object of the type described in intamap-package

Details

conformProjections is a function that attempts to reproject all projected elements in object to one common projection. The function is usually called with an intamap object as argument from createIntamapObject if the parameter confProj = TRUE. Thus it is a function that is usually not necessary to call separately.

The need for this function is because several of the functions in a typical spatial interpolation work flow inside the intamap-package require that the elements have a common projection. In addition, there are some functions which are not able to deal with unprojected spatial objects, i.e. objects with coordinates given in latitude and longitude. conformProjections will hence also attempt to reproject all elements that have coordinates in latitude and longitude, even in the cases where they all have the same projections.

If only one of observations or predictionLocations has a projection (or is longlat), the other one is assumed to be equal. A warning is issued in this case.

The common projection depends on the object that is passed to conformProjections. First of all, if intCRS (see below) is present as an element of the object, all elements will be reprojected to this projection. If not, intCRS will be set equal to the first projection possible in the list below.

intCRS Can be given as a component in object - and is the user-defined common projection used for interpolation

targetCRS Can be given as a component in object - and is the user-defined target projections

predCRS The projection of the predictionLocations in object

obsCRS The projection of the observations
Value

A list of the parameters to be included in the object described in `intamap-package`.

copulaEstimation  ML-estimation of the spatial copula model parameters

Description

Estimates parameters of the spatial copula model using maximum likelihood.

Usage

copulaEstimation(obj,margin,trend,correlation,anisotropy,copula,tol=0.001,...)
Arguments

**obj**
- Intamap object, see description in `intamap-package`

**margin**
- list with the following elements:
  - `params` Starting values for the parameters of the marginal distribution (excluding trend parameters)
  - `lower` Lower bounds for the values of the parameters of the marginal distribution (excluding trend parameters)
  - `upper` Upper bounds for the values of the parameters of the marginal distribution (excluding trend parameters)
  - `name` Name of the family of marginal distributions. Possible names are: "norm", "lnorm", "gev", "t" and "logis"

**trend**
- list with the following elements:
  - `params` Starting values for the parameters of the trend model (location parameter of the marginal distribution)
  - `lower` Lower bounds for the values of the parameters of the trend model
  - `upper` Upper bounds for the values of the parameters of the trend model
  - `F` Design matrix.

**correlation**
- list with the following elements:
  - `model` Correlation function model. Possible models are: "Ste", "Sph", "Gau" and "Exp"
  - `params` Starting values for the parameters of the correlation function model
  - `lower` Lower bounds for the values of the parameters of the correlation function model
  - `upper` Upper bounds for the values of the parameters of the correlation function model

**anisotropy**
- list with the following elements:
  - `params` Starting values for the parameters of geometric anisotropy. If NULL, then no anisotropy is considered.
  - `lower` Lower bounds for the values of the parameters of geometric anisotropy. Usually `c(0,1)`
  - `upper` Upper bounds for the values of the parameters of geometric anisotropy. Usually `c(pi,Inf)`

**copula**
- list with the following elements:
  - `method` Either "norm" or "chisq", depending on which spatial copula model is used, the Gaussian or the chi-squared copula.
  - `params` Only used in case of the chi-squared copula: the squared non-centrality parameter of the non-central chi-squared distribution. Controls how far the chi-squared copula is from the Gaussian copula.
  - `lower` Only used in case of the chi-squared copula: the lower bound for the copula parameter. Usually set to 0
  - `upper` Only used in case of the chi-squared copula: the upper bound for the copula parameter. Usually set to Inf

**tol**
- Tolerance level for the optimization process.

... Arguments to be passed to `optim`. 
**Details**

copulaEstimation performs maximum likelihood estimation of all possible parameters included in the Gaussian and chi-squared spatial copula model: parameters of the predefined family of marginal distributions (including spatial trend or external drift), correlation function parameters, parameters for geometric anisotropy and parameters for the copula (only used for the chi-squared copula model). Due to the large number of variables that need to be optimized, a profile-likelihood approach is used. Although convergence to a global optimum is not assured, the profile-likelihood method makes it less likely that the optimization routine, *optim*, gets stuck in a local optimum. The result of copulaEstimation is a list containing all parameter point estimates that are needed for plug-in spatial prediction. It is advisable to check the output of the algorithm by trying different starting values for the optimization.

**Value**

A list with the following elements:

- **margin**: Same as the input except that the list element "params" now consists of the optimized parameters of the marginal distribution function.
- **trend**: Same as the input except that the list element "params" now consists of the optimized parameters of the trend model.
- **correlation**: Same as the input except that the list element "params" now consists of the optimized parameters of the correlation function model.
- **anisotropy**: Same as the input except that the list element "params" now consists of the optimized parameters of geometric anisotropy.
- **copula**: Same as the input except that the list element "params" now consists of the optimized copula parameters.

createIntamapObject

Create an object for interpolation within the intamap package

Description

This is a help function for creating an object (see intamap-package to be used for interpolation within the intamap-package

Usage

createIntamapObject(observations, obsChar, formulaString,
  predictionLocations = 100, targetCRS, boundaries, boundaryLines,
  intCRS, params = list(), boundFile, lineFile, class = "idw",
  outputWhat, blockWhat = "none", ...)

Arguments

observations
  a SpatialPointsDataFrame, SpatialPixelsDataFrame, SpatialGridDataFrame,
  SpatialLinesDataFrame or SpatialPolygonsDataFrame with observations.
  Note that there are only few methods that can actually handle interpolation of
  observations with a support

obsChar
  list with observation characteristics, used by some interpolation methods

formulaString
  formula that defines the dependent variable as a linear model of independent
  variables; suppose the dependent variable has name z, for ordinary and simple
  kriging use the formula z ~ 1; for universal kriging, suppose z is linearly
  dependent on x and y, use the formula z ~ x + y. The formulaString defaults to
  "value ~ 1" if value is a part of the data set. If not, the first column of the data
  set is used.

predictionLocations
  either a Spatial* object with prediction locations or an integer with the re-
  quested number of prediction locations. If boundaries are supported, the sam-
  pled prediction locations will be sampled within the boundaries.

Examples

data(intamapExampleObject)
## estimate parameters for the copula model
## Not run: copula <- list(method="norm")
anisotropy <- list(lower = c(0, 1), upper = c(pi, Inf), params = c(pi/3, 2))
correlation <- list(model = "Ste", lower = c(0.01, 0.01, 0.01), upper = c(0.99, Inf, 20),
  params = c(0.05, 4, 3))
margin <- list(name = "gev", lower = c(0.01, -Inf), upper = c(Inf, Inf), params = c(30, 0.5))
trend <- list(F = as.matrix(rep(1, 196)), lower = -Inf, upper = Inf, params = 40)
estimates <- copulaEstimation(intamapExampleObject, margin, trend, correlation, anisotropy, copula)
## make predictions at unobserved locations
predictions <- bayescopula(intamapExampleObject, estimates, search = 25,
  calc = list(mean = TRUE, variance = TRUE, excprob = 40, quantile = 0.95))
## End(Not run)
targetCRS  the wanted projection for the interpolated map
boundaries  *SpatialPolygonsDataFrame* with the boundaries of regions in the prediction region
boundaryLines  *SpatialPointsDataFrame* with the boundaries between pairs of regions discretized as points. Will be read from file if *lineFile* is given or will be created from *boundaries* if not.
intCRS  a particular projection requested for the interpolation
params parameters for the interpolation, given as exceptions to the default parameters set in the function *getIntamapParams*. It is also possible to pass a *methodParameters* from an earlier call, as defined from the function *methodParameters*.
boundFile  Filename where boundaries can be found, e.g. a shapefile
lineFile  Filename where paired points on boundaries can be found
class  setting the class(es) of the object, see *intamap-package*
outputWhat List defining the requested type of output. Parameters:
mean = TRUE  Usual kriging prediction
variance = TRUE  Usual kriging error
quantile  The estimated quantile for a certain threshold
excpprob  Exceedance probability for a certain threshold
cumdist  The cumulative distribution for a certain value
MOK  Assumed unbiased prediction using the MOK method for the threshold given. See *unbiasedKrigge*
IWQSEL  Assumed unbiased prediction using the IWQSEL method for the threshold given. See *unbiasedKrigge*
...  Additional prediction types that do not exist in the default parameter set, particularly parameters necessary for new methods within the *intamap-package*.
The list defaults to list (mean = TRUE) for objects of class IDW and list(mean=TRUE, variance = TRUE) for all other objects.
blockWhat List defining particular output for block predictions. These include:
blockMax  logical; whether to predict maximum within block, if block predictions
blockMin  logical; whether to predict minimum within block, if block predictions
fat  Prediction of area within block above a threshold (fat = threshold
blockMaxVar  logical; whether to predict the variance of the prediction of max within the block, similarly it is possible to set blockMinVar = TRUE and fatVar = threshold
...  • Either: other elements that can be used by particular interpolation methods. These are added to the object as named elements.
• Or: elements that have been created in earlier calls to one of the functions in the *intamap-package*, and that are not supposed to change in the second call. By adding these elements to the object in *createIntamapObject*, they can be reused without having to re-estimate them. Typical examples are the elements created from a call to *preProcess*
createIntamapObject

Details

This function is a help function for creating an object (see `intamap-package`) for interpolation within the `intamap-package`. The function uses some default values if certain elements are not included.

If `createIntamapObject` is called without `predictionLocations`, or if a number is given, the function will sample a set of `predictionLocations`. These will be sampled from a regular grid.

targetCRS and intCRS are not mandatory variables, but are recommended if the user wants predictions of a certain projection. intCRS is not necessary if the targetCRS is given and has a projection (is not lat-long). It is recommended to include the argument intCRS if all projected elements are lat-long, as many of the interpolation methods do not work optimal with lat-long data.

The ...-argument can be used for arguments necessary for new methods not being a part of the `intamap-package`. It is also a method for reusing previously calculated elements that can be assumed to be unchanged for the second interpolation.

Value

An object with observations, prediction locations, parameters and possible additional elements for automatic interpolation. The object will have class equal to the value of argument class, and methods in the `intamap-package` will dispatch on the object according to this class.

Examples

```r
# set up data:
data(meuse)
coordinates(meuse) = ~x+y
meuse$value = log(meuse$zinc)
data(meuse.grid)
gridded(meuse.grid) = ~x+y
proj4string(meuse) = CRS("+init=epsg:28992")
proj4string(meuse.grid) = CRS("+init=epsg:28992")

# set up intamap object:
idwObject = createIntamapObject(
observations = meuse,
predictionLocations = meuse.grid,
)
```
This function estimates geometric anisotropy parameters for 2-D scattered data using the CTI method.

Usage

`estimateAnisotropy(object, depVar, formulaString)`

Arguments

- **object**: (i) An Intamap type object (see `intamap-package`) containing one `SpatialPointsDataFrame` data frame named observations which includes the observed values (ii) or a `SpatialPointsDataFrame` which includes both coordinates and observations.
- **depVar**: name of the dependent variable; this is used only in case (ii).
- **formulaString**: formula that defines the dependent variable as a linear model of independent variables, only used for case (ii); suppose the dependent variable has name z, for ordinary and simple kriging use the formula `z ~ 1`; for universal kriging, suppose z is linearly dependent on x and y, use the formula `z ~ x + y`. The `formulaString` defaults to `"value ~ 1"` if value is a part of the data set. If not, the first column of the data set is used.

Details

Given the input object that defines N coordinate pairs (x,y) and observed values (z), this method estimates the geometric anisotropy parameters. Geometric anisotropy is a statistical property, which implies that the iso-level contours of the covariance function are elliptical. In this case the anisotropy is determined from the anisotropic ratio (R) and the orientation angle (θ) of the ellipse.

Assuming a Cartesian coordinate system of axes x and y, θ represents the angle between the horizontal axis and PA1, where PA1 is one of the principal axes of the ellipse, arbitrarily selected (PA2 will denote the other axis). R represents the ratio of the correlation along PA1 divided by the correlation length PA2. Note that the returned value of R is always greater than one (see value below.)

The estimation is based on the Covariance Tensor Identity (CTI) method. In CTI, the Hessian matrix of the covariance function is estimated from sample derivatives. The anisotropy parameters are estimated by explicit solutions of nonlinear equations that link (R,θ) with ratios of the covariance Hessian matrix elements.

To estimate the sample derivatives from scattered data, a background square lattice is used. The lattice extends in the horizontal direction from x.min to x.max where x.min (x.max) is equal to the
estimateAnisotropy

minimum (maximum) x-coordinate of the data, and similarly in the vertical direction. The cell step in each direction is equal to the length of the lattice to the respective direction divided by the square root of N.

BiLinear interpolation, as implemented in akima package, is used to interpolate the field's z values at the nodes of the lattice.

The CTI method is described in detail in (Chorti and Hristopulos, 2008).

Note that to be compatible with gstat the returned estimate of the anisotropy ratio is always greater than 1.

For observations assumed to have a trend, the trend is first subtracted from the data using universal kriging. This is an approximation, as the trend subtraction does not take anisotropy into account.

Value

(i) If the input is an Intamap object, the value is a modification of the input object, containing a list element anisPar with the estimated anisotropy parameters. (ii) if the input is a SpatialPointsDataFrame, then only the list anisPar is returned. The list anisPar contains the following elements:

- **ratio**: The estimate of the anisotropy ratio parameter. Using the degeneracy of the anisotropy under simultaneous ratio inversion and axis rotation transformations, the returned value of the ratio is always greater than 1.

- **direction**: The estimate of the anisotropy orientation angle. It returns the angle between the major anisotropy axis and the horizontal axis, and its value is in the interval (-90,90) degrees.

- **Q**: A 3x1 array containing the sample estimates of the diagonal and off-diagonal elements (Q11,Q22,Q12) of the covariance Hessian matrix evaluated at zero lag.

- **doRotation**: Boolean value indicating if the estimated anisotropy is statistically significant. This value is based on a statistical test of the isotropic (R=1) hypothesis using a non-parametric approximation for the 95 percent confidence interval for R. This approximation leads to conservative (wider than the true) estimates of the confidence interval. If doRotation==TRUE then an isotropy restoring transformation (rotation and rescaling) is performed on the coordinates. If doRotation==FALSE no action is taken.

Note

This function uses akima package to perform "bilinear" interpolation. The source code also allows other interpolation methods, but this option is not available when the function is called from within INTAMAP.

In the gstat package, the anisotropy ratio is defined in the interval (0,1) and the orientation angle is the angle between the vertical axis and the major anisotropy axis, measured in the clockwise direction. If one wants to use ordinary kriging inside INTAMAP the necessary transformations are performed in the function estimateParameters.automap. If one wants to use ordinary kriging in the gstat package (but outside INTAMAP) the required transformations can be found in the source code of the estimateParameters.automap function.
estimateParameters

estimateParameters  Automatic estimation of correlation structure parameters

Description
Function to estimate correlation structure parameters. The actual parameters depend on the method used.

Usage
## S3 method for class 'automap'
estimateParameters(object, ...)
## S3 method for class 'copula'
estimateParameters(object, ...)
## Default S3 method:
estimateParameters(object, ...)
## S3 method for class 'idw'
estimateParameters(object, ...)
## S3 method for class 'linearVariogram'
estimateParameters(object, ...)
Arguments

object

an intamap object of the type described in `intamap-package`

... other arguments that will be passed to the requested interpolation method. See the individual methods for more information. Some parameters that are particular for some methods:

idpRange range of idp (inverse distance weighting power) values over which to optimize mse (idw-method)
nfolds number of folds in n-fold cross validation (idw-method)
lambda lambda parameter for boxcox-transformation (transGaussian method)
significant logical; if TRUE only transform if any of the four tests described under `interpolate` are TRUE (transGaussian method)

Details

The function `estimateParameters` is a wrapper around different methods for estimating correlation parameters to be used for the spatial prediction method `spatialPredict`. Below are some details about and/or links to the different methods currently implemented in the `intamap-package`.

**automap**
It is possible but not necessary to estimate variogram parameters for this method. If `estimateParameters` is called with an object of class `automap`, `autofitVariogram` will be called. If object already includes a variogram model when `spatialPredict` is called, `krige` in the `gstat`-package will be called directly. The user can submit an argument `model` with the model(s) to be fitted.

**copula**
Finding the best copula parameters using `copulaEstimation`

default a default method is not really implemented, this function is only created to give a sensible error message if the function is called with an object for which no method exist

**idw**
fits the best possible idw-power to the data set by brute force searching within the idpRange

**linearVariogram**
this function just returns the original data, no parameter fitting is necessary for linear variogram kriging

**transGaussian**
Finding the best model parameters for transGaussian kriging (krigeTg). This means finding the best lambda for the boxcox-transformation and the fitted variogram parameters for the transformed variable. If significant = TRUE will lambda only be estimated if the data show some deviation from normality, i.e., that at least one of the tests described under `interpolate` is TRUE. Note that transGaussian kriging is only possible for data with strictly positive values.

**yamamoto**
a wrapper around `estimateParameters.automap`, only to assure that there is a method also for this class, difference to automap is more important in `spatialPredict`

It is also possible to add to the above methods with functionality from other packages, if wanted. You can also check which methods are available from other packages by calling

```r
> methods(estimateParameters)
```
evaluateParameters

Value

a list object similar to object, but extended with correlation parameters.

   nfold=3) # faster
idwObject$inverseDistancePower
Description

Function that takes time samples function that can read intamap objects

Usage

```r
estimateTimeModel(FUN, class, formulaString, debug.level, ...)
```

Arguments

- `FUN`: A string with function’s name
- `class`: class of intamapObject, which interpolation method to be used.
- `formulaString`: the formula of the request, mainly to see if the request has independent variables.
- `debug.level`: if debug.level >= 1, the function will store tables with the prediction times for each model in the workspace.
- `...`: other arguments as defined in the `createIntamapObject` function

Details

This function uses `createIntamapObject` function to create synthetic data, in order to take time samples for the function with string name "FUN". The calculated model is stored, as an element of a list, in a local file (workspace for now) and it’s used in order to give quick time estimates.

Value

The function does not return a variable but stores the result in an element list with the same name.

References

generateTimeModels  Generate time models

Description

function that generates time models and saves them in workspace.

Usage

generateTimeModels(genClasses = NULL, noGenClasses = NULL, nSam = 1, test = FALSE, debug.level = 0)

Arguments

genClasses  list of particular classes for which time models should be generated
noGenClasses list of particular classes for which time models should not be generated
nSam  number of attempts to be tried for each combination of predictions and observations, defaults to 1, higher number should be used for better accuracy. nSam/2 is used for copulas, to reduce computation time.
test  logical; if true, the time models are generated based on fewer iterations, for speed
debug.level  if debug.level >= 1, the function will store tables with the prediction times for each model in the workspace.

Details

This function calculates a time model for different interpolation types in the intamap-package and returns a list object with the estimated models. It's users responsibility to store the model in the workspace. The normal procedure would be to run the function without arguments. However, it is both possible to define a list for which classes the user want to generate models, or a list of classes that are not of interest.

The time model is based on creation of a set of synthetical data sets of different size, both regarding number of observations and prediction locations. The function will estimate parameters and make predictions with the different combinations, and for each method, fit a local polynomial regression model (loess)

This model can then be used by predictTime to estimate the prediction time for an interpolation request with a certain number of observations and prediction locations.

Value

The function generates a timeModels object, which can be used to estimate prediction times for different requests to the interpolate function in the intamap-package, via predictTime.
References

Examples

```
## Not run:
timeModels=generateTimeModels()
q("yes")
## restart R in the same directory

## End(Not run)
```

getIntamapParams

Setting parameters for the intamap package

Description

This function sets a range of the parameters for the intamap package, to be included in the object described in intamap-package

Usage

getIntamapParams(oldPar,newPar,...)

Arguments

oldPar An existing set of parameters for the interpolation process, of class IntamapParams or a list of parameters for modification of the default parameters

newPar A list of parameters for updating oldPar or for modification of the default parameters. Possible parameters with their defaults are given below

... Individual parameters for updating oldPar or for modification of the default parameters. Possible parameters with their defaults are given below

doAnisotropy = FALSE Defining whether anisotropy should be calculated

removeBias = NA Defining whether biases should be removed, and in case yes, which ones (localBias and regionalBias implemented

addBias = NA Defining which biases to be added in the postProcess function.

This has not yet been implemented.

biasRemovalMethod = "LM" character; specifies which methods to use to remove bias. See below.

doSegmentation = FALSE Defining if the predictions should be subject to segmentation. Segmentation has been implemented, but not the use of it.

testMean logical; for copula method only; whether or not the predictive means (if calculated) should be tested for being reasonable
nmax = 50 for local kriging: the number of nearest observations that should be used for a kriging prediction or simulation, where nearest is defined in terms of the space of the spatial locations. By default, 50 observations are used.

ngrid = 100 The number of grid points to be used if an Averaged Cumulative Distribution Function (ACDF) needs to be computed for unbiased kriging

nsim=100 Number of simulations when needed

block = numeric(0) Block size; a vector with 1, 2 or 3 values containing the size of a rectangular in x-, y- and z-dimension respectively (0 if not set), or a data frame with 1, 2 or 3 columns, containing the points that discretize the block in the x-, y- and z-dimension to define irregular blocks relative to (0,0) or (0,0,0) - see also the details section of predict.gstat. By default, predictions or simulations refer to the support of the data values.

processType = "gaussian" If known - the distribution of the data. Defaults to gaussian, analytical solutions also exists in some cases for logNormal. This setting only affects a limited number of methods, e.g. the block prediction

confProj = FALSE If set, the program will attempt conform projections in preprocess, calling the function conformprojections.

debug,level = 0 Used in some functions for giving additional output. See individual functions for more information.

nclus = 1 it is possible to use parallel processing for some interpolation methods (currently only the copula method), nclus defines the number of processes to spawn. This requires previous installation of the doparallel package

... Additional parameters that do not exist in the default parameter set, this could be parameters necessary for new methods within or outside the intamap-package

Value

A list of the parameters with class intamapParams to be included in the object described in intamap-package

Note

This function will mainly be called by createIntamapObject, but can also be called by the user to create a parameter set or update an existing parameter set. If none of the arguments is a list of class IntamapParams), the function will assume that the argument(s) are modifications to the default set of parameters.

If the function is called with two lists of parameters (but the first one is not of class IntamapParams) they are both seen as modifications to the default parameter set. If they share some parameters, the parameter values from the second list will be applied.

```

**Description**

Salted (slightly modified) observations from the European gamma radiation network

**Usage**

```r
data(intamap)
```

**Details**

The data set is a salted data set from the European gamma radiation network [http://eurdep.jrc.ec.europa.eu/Basic/Pages/Public/Home/Default.aspx](http://eurdep.jrc.ec.europa.eu/Basic/Pages/Public/Home/Default.aspx). Salted does in this context mean that all locations and observation values have been randomized through addition of a random value.

**References**

**intamapExampleObject**  
*Simulated Intamap Object*

**Description**

Intamap object of class "copula" containing a simulated data set with 196 spatial locations.

**Usage**

```r
data(intamapExampleObject)
```

**Details**

The data set is a realization of a random field generated using a Gaussian copula and generalized extreme value distributed margins (location=40, shape=0.5, scale=30). The correlation function is Matern (Stein’s representation) with range=4, kappa=3 and nugget=0.05. Furthermore, there is geometric anisotropy with direction=pi/3 and ratio=2.
interpolate is a function that interpolates spatial data

Usage

```r
interpolate(observations, predictionLocations, outputWhat = list(mean = TRUE, variance = TRUE), obsChar = NA, methodName = "automatic", maximumTime = 30, optList = list(), cv = FALSE)
interpolateBlock(observations, predictionLocations, outputWhat, blockWhat = "none", obsChar = NA, methodName = "automatic", maximumTime = 30, optList = list())
```

Arguments

- **observations**: observation data, object of class `SpatialPointsDataFrame`. The observation to be interpolated has to be identified through the column name `value`.
- **predictionLocations**: prediction locations, object of class `SpatialPoints`, `SpatialPixels` or `SpatialGrid`, or the number of predictionLocations to be sampled from the boundaries of the observations.
- **outputWhat**: list with names what kind of output is expected, e.g. `outputWhat = list(mean=TRUE, variance=TRUE, nsim=50)`.

References

blockWhat  List defining particular output for block predictions. See createIntamapObject
obsChar  list with observation characteristics, used by some interpolation methods
methodName  name of interpolation method to be used, see spatialPredict for more details, or automatic, to let the method be decided by the program, based on maximum-Time and type of variables input
maximumTime  the maximum time available for interpolation, will be compared to the result of predictTime for the requested method, or for finding the best interpolation method able to finish within this time
optList  list: further options, mainly passed to createIntamapObject as the argument params, directly as arguments, but some are used locally in interpolate and interpolateBlock:

  formulaString  passed as argument to createIntamapObject, if no formulaString is given, it will default to value~1 if observations has a column named value or to col1 ~ 1 where col1 is the first column of the observations

    set.seed  the possibility to pass a seed value to interpolate, to assure reproducible results also for methods relying on random numbers

    methodParameters  methodParameters from an earlier run, see also methodParameters

    model  defining which variogram model(s) to fit when methodName = "automap"

cv  If cross-validation should be done

Details

The functions interpolate and interpolateBlock are particularly implemented for being called by a Web Processing Server (WPS), but they can also be used interactively. The only necessary arguments are observations and predictionLocations. It is also recommended to set outputWhat, and blockWhat if necessary. If outputWhat contains nsim, the return table will also contain a number of realisations, for methods able to return simulations.

interpolate can use different interpolation methods for the result. The function will internally call the following functions which can be method specific.

  * preProcess
  * estimateParameters
  * spatialPredict
  * postProcess

An indication of available methods can be given by methods(estimateParameters) or methods(spatialPredict). The method can be set through the argument methodName, or through the built-in automatic selection method. There are different criteria that helps in selecting the right method for a particular data set. There are four methods that are available for the automatic choice: automap, psgp (from the separate package psgp) copula and transgaussian are the possibilities. First of all, if observation errors are present, the psgp method is preferred. If not, it is checked whether the data appear to deviate significantly from normality. This is assumed to be the case if any of the tests below are TRUE:
test[1] = length(boxplot.stats(dataObs)$out)/length(dataObs) > 0.1

g = boxcox(dataObs ~ QLlambda|seq(-2.5, 2.5, len=101), plotit=FALSE)$y

where *fivenum* defines the Tukey five number statistic and *IQR* finds the interquartile range of the data. If the minimum of dataObs is <= 0, min(dataObs) + sdev(dataObs) is added to all values. At last, the function calls *predictTime* for an estimate of the prediction time. If any of the tests above were true and the estimated prediction time for copula prediction is below *maximumTime*, the copula method is chosen. If any of the tests were TRUE and the estimated prediction time is too long, *transGaussion* kriging is chosen, as long as all values are above zero. If any of the tests are true for a set of observations with negative or zero-values, *automap* is chosen, but a warning is issued.

The element *methodParameters* in the object being returned is a string that makes it possible to regenerate the variogram model or the copula parameters in *createIntamapObject*. This is particularly useful when the function is called through a WPS, when the element with the estimated parameters cannot be preserved in a state that makes it possible to use them for a later call to *interpolate*.

The possibility for doing parallel processing is enabled for some of the main methods. To be able to take advantage of multiple CPUs on a computer, the package *doparallel* must be downloaded, additionally the parameter *nclus* must be set to a value larger than 1. Parallel computation is not taken into account when estimating the prediction times.

**Value**

An intamap object, which is a list with elements, see *intamap-package*. The exact number and names of these elements might vary due to different methods applied, but the list below shows the most typical:

- **observations** the observations, as a Spatial*DataFrame*
- **predictionLocations** the prediction locations, as a Spatial-object
- **formulaString** the relationship between independent and dependent variables, value or obs used if not given
- **outputWhat** a list of the prediction types to return
- **anisPar** the estimated anisotropy parameters
- **variogramModel** the estimated parameter for the method, can also be e.g. *copulaParams* for the copula method or *inverseDistancePower* for inverse distance power method.
- **methodParameters** a string, that when parsed, can be used to regenerate the variogram model or copula parameters. Useful for repeated calls to interpolate when it is not necessary to reestimate the parameters.
- **predictions** a Spatial*DataFrame with predictions, for most methods with a format equal to the output from *krige* with predicted mean and variance as *var1.pred* and *var1.var*
methodParameters

outputTable  a matrix, organized in a convenient way for the calling WPS; first row: x-coordinates, second row: y-coordinates; further rows: output elements as specified by outputWhat

processDescription  some textual descriptions of the interpolation process, including warnings

createIntmapObject, estimateParameters, spatialPredict, intamap-package

Examples

data(meuse)
coordinates(meuse) = ~x+y
meuse$value = meuse$zinc
data(meuse.grid)
grided(meuse.grid) = ~x+y
x = interpolate(meuse, meuse.grid, list(mean=TRUE, variance=TRUE))
summary(t(x$outputTable))
Arguments

object a list object. Most arguments necessary for interpolation are passed through this object. See *intamap-package* for further description of the necessary content of this variable.

Details

The function creates a text-string that makes it possible to add the method parameters (anisotropy and idw-parameter, variogram model or copula parameters) to the object in a later call to `createintamapObject` or `interpolate` without having to re-estimate the parameters. This function is particularly useful when `interpolate` is called from a Web Processing Service, and the user wants to reuse the method parameters. The function is mainly assumed to be called from within `interpolate`.

The default method assumes a variogram model of *gstat* type, e.g. a variogram similar to what can be created with a call to `vgm`. Also *psgp* uses this variogram model.

Value

A string that, when parsed, will recreate the `methodParameters`.

krigingObject$variogramModel
krigingObject2$variogramModel
plotIntamap

plotIntamap  plot intamap objects

Description

Plotting function for intamap-objects of the type described in intamap-package

Usage

plotIntamap(object, zcol = "all", sp.layout = NULL, plotMat = c(2,2), ...)  
## S3 method for class 'copula'
plot(x, ...)
## S3 method for class 'idw'
plot(x, ...)
## S3 method for class 'automap'
plot(x, ...)

## S3 method for class 'linearVariogram'
plot(x, ...)
## S3 method for class 'transGaussian'
plot(x, ...)
## S3 method for class 'yamamoto'
plot(x, ...)

Arguments

object  a list object. Most arguments necessary for interpolation are passed through this object. See intamap-package for further description of the necessary content of this variable
x  intamap object, when plot is called directly
zcol  a list of column names to be plotted; if equal to all, the column names will correspond to all possible column names from outputWhat (see createIntamapObject)
sp.layout  an object that can contain lines, points and polygons that function as extra layout; see spplot for more information
plotMat  an array of length two with the number of rows and columns of plots per page
...  other parameters that can be passed to other plot functions (e.g. plot, spplot, automapPlot and xyplot

Details

All the plot methods above are simple wrapper functions around the plotIntamap function.

Value

A plot of some of the elements of object. This will typically be the sample variogram and the fitted variogram model (if a method based on variograms has been used) and all the predictions.
postProcess

Author(s)
Jon Olav Skoien

References

Examples
```r
data(meuse)
meuse$value = log(meuse$zinc)
data(meuse.grid)
coordinates(meuse) = ~x+y
coordinates(meuse.grid) = ~x+y
object = interpolate(meuse, meuse.grid,
outputWhat = list(mean = TRUE, variance = TRUE,  
excprob = 7, excprob = 8, quantile = 0.9, quantile = 0.95), 
methodName = "automap")

plot(object)
```

---

postProcess  pre-process data

Description
post-processing of data for the intamap-package. The function will typically call other functions for adding back biases, aggregation etc.

Usage
```r
## Default S3 method:
postProcess(object, ...)
## S3 method for class 'idw'
postProcess(object, ...)
```

Arguments
- **object**
a list object. Most arguments necessary for interpolation are passed through this object. See intamap-package for further description of the necessary content of this variable
- **...**
other parameters that can be passed to functions called from preProcess

Details
The function postProcess includes code for postprocessing an object after interpolation. The function can easily be replaced by more specific methods relevant for a certain data set, doing more data specific things in addition to what is done in the default method.
predictTime

Value
An object of same type as above, but with new elements. Most important from the default method is the outputTable, a matrix, organized in a convenient way for the calling WPS; first row: x-coordinates, second row: y-coordinates; further rows: output elements as specified by outputWhat (see createIntamapObject).

predictTime | Time prediction for intamap package methods

Description
Functions that give a time estimate for an intamap function given the number of observations and predictionLocations.

Usage
predictTime(nObs, nPred, class, formulaString, calibration=FALSE, outputWhat, FUN = "spatialPredict", ...)

Arguments
nObs | An integer or an array of integers containing the number of observations.
nPred | An integer or an array of integers containing the number of predictions.
class | class of intamapObject, which interpolation method to be used.
formulaString | the formula of the request, mainly to see if the request has independent variables.
calibration | enables or disables time calibration - not properly implemented yet.
outputWhat | List defining the requested type of output, see createIntamapObject.
FUN | A string with the intamap functions name, now obsolete.
... | other arguments needed to define the intamap object.

Details
The function is based on timeModels being available in the workspace. This is a loess-model that has been fitted to different calls to a range of interpolation requests with synthetically generated data in generateTimeModels.
Value

An integer or an array of integers with the predicted times.

Note

RUN FIRST generateTimeModels() or estimateTimeModel() in order to save time Models to workspace. It might take some time!

References

Description

pre-processing of the data for the intamap-package package.

Usage

```r
## Default S3 method:
preProcess(object, ...)
## S3 method for class 'idw'
preProcess(object, ...)
```

Arguments

- `object` see intamap-package; list that should at least contain (i) an element called observations of class SpatialPointsDataFrame. The measured values should be named value, and (ii) an element `params` of class `list`, by calling the function `getIntamapParams`. (iii) Usually, the object will also contain an element called predictionLocations, of a class extending Spatial.
- `...` Additional parameters

Details

The function `preProcess` includes code for preprocessing an object before interpolation. The function can easily be replaced by more specific methods relevant for a certain data set. Functions can be called from `preProcess` according to the settings in parameters in the object, set by the function `getIntamapParams`.

Value

The input object is returned, after its components have been pre-processed.
**rotateAnisotropicData**

**Author(s)**

Jon Olav Skoien

**References**

---

**Description**

This function applies an isotropic transformation of the coordinates specified in `object`.

**Usage**

rotateAnisotropicData(object, anisPar)

**Arguments**

- **object**
  - (i) An Intamap type object (see `intamap-package`) containing one `SpatialPointsDataFrame` data frame named observations which includes the observed values
  - (ii) or a `SpatialPointsDataFrame` which includes both coordinates and observations
  - (iii) `SpatialPoints` which includes only coordinates to be rotated.

- **anisPar**
  - An array containing the anisotropy parameters (anisotropy ratio and axes orientation) (see `estimateAnisotropy`) for the rotation. If `object` is the output of `estimateAnisotropy` function, these parameters are part of `object`. In cases (ii) and (iii) `anisPar` defines the two anisotropy parameters. For the definition of the anisotropy parameters see `estimateAnisotropy`.

**Details**

This function performs a rotation and rescaling of the coordinate axes in order to obtain a new coordinate system, in which the observations become statistically isotropic. This assumes that the estimates of the anisotropy ratio and the orientation angle provided in `anisPar` are accurate.

**Value**

- (i) A modified object with transformed coordinates if `rotateAnisotropicData` is called with an Intamap object as input (see `intamap-package`) or (ii) the transformed coordinates if a `SpatialPointsDataFrame` is used as input or (iii) the transformed coordinates if a `SpatialPoints` object is the input.

estimateAnisotropy

Examples

```r
library(hstat)
data(sic2004)
coordinates(sic.val) <- x+y
sic.val$value = sic.val$dayx

anisPar <- estimateAnisotropy(sic.val)
print(anisPar)

rotatedObs <- rotateAnisotropicData(sic.val, anisPar)

newAnisPar <- estimateAnisotropy(rotatedObs)
print(newAnisPar)
```

spatialPredict

Spatial prediction

Description

spatialPredict is a generic method for spatial predictions within the intamap-package. A series of methods have been implemented, partly based on other R-packages (as krig), other methods have been developed particularly for the INTAMAP project. The object has to include a range of variables, further described in intamap-package. The prediction method is chosen based on the class of the object.

Usage

```r
## S3 method for class 'automap'
spatialPredict(object, nsim = 0, ...)
## S3 method for class 'copula'
spatialPredict(object, ...)
## Default S3 method:
```
spatialPredict

spatialPredict(object, ...)
## S3 method for class 'idw'
spatialPredict(object, ...)
## S3 method for class 'linearVariogram'
spatialPredict(object, nsim = 0, ...)

## S3 method for class 'transGaussian'
spatialPredict(object, nsim = 0, ...)
## S3 method for class 'yamamoto'
spatialPredict(object, nsim = 0, ...)

Arguments

- **object**: a list object. Most arguments necessary for interpolation are passed through this object. See `intamap-package` for further description of the necessary content of this variable.
- **nsim**: number of simulations to return, for methods able to return simulations.
- **...**: other arguments that will be passed to the requested interpolation method. See the individual interpolation methods for more information.

Details

The function `spatialPredict` is a wrapper around different spatial interpolation methods found within the `intamap-package` or within other packages in R. It is for most of the methods necessary to have parameters of the correlation structure included in `object` to be able to carry out the spatial prediction. Below are some details about particular interpolation methods:

- **default**: a default method is not really implemented, this function is only created to give a sensible error message if the function is called with an object for which no method exist.
- **automap**: If the object already has an element `variogramModel` with variogram parameters, `krige` is called. If the this is not a part of the object, `estimateParameters` is called to create this element.
- **copula**: spatial prediction using `bayesCopula`.
- **idw**: applies inverse distance modelling with the idp-power found by `estimateParameters.idw`.
- **linearVariogram**: this function estimates the process using an unfitted linear variogram; although variance is returned it can not be relied upon.
- **transGaussian**: spatial prediction using `krigeTg`.
- **yamamoto**: spatial prediction using `yamamotoKrige`.

It is also possible to add to the above methods with functionality from other packages, if wanted. You can also check which methods are available from other packages by calling

> `methods(spatialPredict)`

Value

A list object similar to `object`, but extended with predictions at a the set of locations defined `object`.

summaryIntamap

summary intamap objects

Description

summary function for intamap-objects of the type described in intamap-package
Usage

summaryIntamap(object, ...)
## S3 method for class 'copula'
summary(object, ...)
## S3 method for class 'idw'
summary(object, ...)
## S3 method for class 'automap'
summary(object, ...)

## S3 method for class 'linearVariogram'
summary(object, ...)
## S3 method for class 'transGaussian'
summary(object, ...)
## S3 method for class 'yamamoto'
summary(object, ...)

Arguments

object a list object. Most arguments necessary for interpolation are passed through this object. See intamap-package for further description of the necessary content of this variable

... parameters to be passed to the default summary function for each element

Value

A summary of some of the elements of object.

Jon Olav Skoien

References

Description

This is a standard model for estimating the prediction time within the intamap-package. It was created by the function generateTimeModels, on a 64 bits Linux server running R version 2.9.0 and intamap-package version 1.1.15.

The prediction time will depend on the speed of the local machine, on the version of R and intamap-package, and on the installed libraries. It is therefore strongly recommended to run generateTimeModels on
the local machine and store the result in the workspace if the predicted interpolation time is of real interest. `timeModels` in the workspace will be chosen if available. It is not necessary to load the data set, this happens automatically in `predictTime` if `timeModels` if the object is not already existing in the workspace.

**Usage**

```r
data(timeModels)
```

**unbiasedKrig**

Unbiased kriging

**Description**

`unbiasedKrig` is a function for modifying a kriging prediction to a prediction that can be assumed to be unbiased for a certain threshold.

**Usage**

```r
unbiasedKrig(object, formulaString, observations, predictionLocations, model, outputWhat, nmax, nsim, yamamoto, iwqmaxit = 500, iwqCpAddLim = 0.0001, debug.level, ...)
```

**Arguments**

- `object` either an object of the intamap type (see `intamap-package` for further description of the necessary content of this variable) or the output from the function `krig` in `gstat`. If the object is a result from the intamap procedure `spatialPredict`, the remaining arguments are not necessary.
- `formulaString` formula that defines the dependent variable as a linear model of independent variables; suppose the dependent variable has name `z`, for ordinary and simple kriging use the formula `z~1`; for universal kriging, suppose `z` is linearly dependent on `x` and `y`, use the formula `z~x+y`
- `observations` a `Spatial*DataFrame` with observations; should contain the dependent variable, independent variables, and coordinates
unbiasedKriging

predictionLocations

the predictionLocations, only necessary if the method is "IWQSEL" and formulaString contains independent variables. Should preferentially be a grid if the method is "IWQSEL".

model

variogram model of dependent variable (or its residuals), defined by a call to vgm or autofitVarioGram

outputWhat

Argument with type of unbiasedness method ("MOK" or "IWQSEL") and the thresholds.

nmax

for local kriging: the number of nearest observations that should be used in simulations for the "IWQSEL" method in terms of the space of the spatial locations. Defaults to nmax = 10 when object is a SpatialDataFrame.

nsim

number of simulations necessary if the method is "IWQSEL". Defaults to nsim = 100 when object is a SpatialDataFrame.

yamamoto

logical describing if the yamamoto approach is to be used in simulations. Defaults to yamamoto = FALSE when object is a SpatialDataFrame.

iwqmaxit

maximum number of iterations in iwqsel

iwqCpAddLim

convergence criteria in iwqsel

debugNlevel

debug level, passed to subfunctions

...

other arguments that will be passed to subfunctions

Details

It is a fact that predictions from kriging tend to be biased towards the mean of the process. The function unbiasedKriging is a function that adds one or more predictions to the original output, which are assumed to be unbiased relative to a certain threshold. The two methods supported are the IWQSEL-method (Craigmile, 2006) and MOK (Skoien et al., 2008).

Value

an object of type intamap, as described in intamap-package, or a SpatialDataFrame with one or more new prediction columns, representing different methods and thresholds.

yamamotoKriging

kriging and simulation with alternative kriging variance

Description

ordinary kriging and simulation with an alternative kriging variance

Usage

yamamotoKriging(formula, Obs, newPoints, model, nsim = 0, nmax = 20)

Arguments

formula formula that defines the dependent variable as a linear model of independent variables; suppose the dependent variable has name z, for ordinary and simple kriging use the formula z~1; only ordinary kriging is currently implemented, formula is hence mainly used to identify the dependent variable

Obs SpatialPointsDataFrame with observations

ewPoints Spatial object with prediction locations, either points or grid

model variogram model - of the type that can be found by a call to vgm

nsim integer; if set to a non-zero value, conditional simulation is used instead of kriging interpolation. For this, sequential Gaussian simulation is used, following a single random path through the data.

nmax for local kriging: the number of nearest observations that should be used for a kriging prediction or simulation, where nearest is defined in terms of the space of the spatial locations. By default, all observations are used.
Details

The term `yamamotokrige` comes from the paper of Yamamoto (2000) where he suggests using local variance around the kriging estimate (weighted with the kriging weights) as an alternative kriging variance. This as a solution to more reliable estimates of the kriging variance also when the stationarity assumption has been violated. The method was applied by Skoien et al. (2008), who showed that it can have advantages for cases where the stationarity assumption behind kriging is violated.

If the number of observations is high, it is recommended have `nmax` lower. This is partly because the method relies on positive kriging weights. The method to do this adds the norm of the largest negative weight to all weights, and rescales. This tends to smooth the weights, giving a prediction closer to the average if a too large number of observation locations is used.

Value

Either a `Spatial*DataFrame` with predictions and prediction variance, in the columns `var1.pred` and `var1.var`, together with the classical ordinary kriging variance in `var1.ok`, or simulations with column names `simx` where `x` is the number of the simulation.

Examples

```r
library(gstat)
library(automap)
data(sic2004)
coordinates(sic.val) = ~x+y
coordinates(sic.test) = ~x+y
variogramModel = autofitVariogram(joker-1,sic.val)$var_model
newData = yamamotokrige(joker-1,sic.val,sic.test,variogramModel,nmax = 20)
summary(newData)
plot(sqrt(var1.ok)-var1.pred,newData)
# Kriging variance the same in regions with extreme values
plot(sqrt(var1.var)-var1.pred,newData)
# Kriging standard deviation higher for high predictions (close to extreme values)
```
