Description

Fits non-crossing regression quantiles as a function of linear covariates and smooth terms via B-splines with difference penalties.

Details

Package: quantregGrowth
Type: Package
Version: 0.4-3
Date: 2018-09-18
License: GPL

Package quantregGrowth allows estimation of growth charts via quantile regression. Given a set of percentiles, gcrq estimates non-crossing quantile curves as a flexible function of quantitative covariates (typically age), and possibly additional linear terms. To ensure flexibility, B-splines with a difference $L_1$ penalty are employed to estimate nonparametrically the curves; additionally monotonicity constraints may be also set. plot.gcrq displays the fitted lines along with observations and pointwise confidence intervals.

gcrq

Growth charts regression quantiles

Description

Estimation of nonparametric growth charts via quantile regression. Quantile curves are estimated via B-splines with a $L_1$ penalty on the spline coefficient differences, while non-crossing and monotonicity restrictions are set to obtain estimates more biologically plausible. Linear terms are allowed in the model specification.

Usage

gcrq(formula, tau = c(0.1, 0.25, 0.5, 0.75, 0.9), data, subset, weights,
     na.action, transf=NULL, y = TRUE, interc=FALSE,
     foldid = NULL, nfolds = 10, cv = TRUE, n.boot=0, eps=.0001, ...)

Arguments

formula a standard R formula to specify the response in the left hand side, and the covariates in the right hand side. See Details.
tau a numeric vector to specify the percentiles of interest. Default to probability values (.1,.25,.5,.75,.9).
data the dataframe where the variables required by the formula, subset and weights arguments are stored.
subset optional. A vector specifying a subset of observations to be used in the fitting process.
weights optional. A numeric vector specifying weights to be assigned to the observations in the fitting process. Currently unimplemented.
na.action a function which indicates how the possible ‘NA’s are handled.
transf  an optional character string (with "y" as argument) meaning a function to apply to the response variable before fitting. E.g. "log(y+0.1)". It can be useful to guarantee fitted values within a specified range. If provided, the resulting object will include the corresponding inverse (numerically computed) to be used to back transform predictions (see argument transform in predict.gcrq and plot.gcrq).

y    logical. If TRUE (default) the returned object includes also the responses vector.

interc logical. If formula includes a "ps" term, interc=TRUE means that a model intercept is also estimated. If this is the case, a very small ridge-type penalty is exploited to allow estimation with a design matrix containing both a full B-spline basis and a column of ones. interc=TRUE overwrites the intercept specification in the formula (e.g., ~0+...), and it is ignored if the model does not include a "ps" term.

foldid optional. A numeric vector identifying the group labels to perform cross validation to select the smoothing parameter. Ignored if the lambda argument in ps() is not a vector.

nfolds optional. If foldid is not provided, it is scalar specifying the number of ‘folds’ (groups) which should be used to perform cross validation to select the smoothing parameter. Default to 10, but it is ignored if the lambda argument in ps() is not a vector.

cv logical. If TRUE (default) and there is a single smooth term wherein lambda is a vector, the returned object includes also the matrix cv having number of rows equal to length of lambda and number of columns equal to nfolds. Ignored if the lambda argument in ps() is not a vector.

n.boot Number of nonparametric (cases resampling) bootstrap samples to be used. Notice that the smoothing parameter (if relevant) does change throughout the bootstrap replicates. Set n.boot>0 if you plan to plot the fitted quantiles along with pointwise confidence intervals.

eps A small positive constant to ensure noncrossing curves. Use it at your risk! If eps is large, the resulting fitted quantile curves could appear unreasonable.

... further arguments.

Details

The function fits regression quantiles at specified percentiles given in tau as a function of covariates specified in the formula argument. The formula may optionally include several ps terms to model nonlinear relationships with quantitative covariates, usually age in growth charts. When the lambda argument in ps() is scalar, it represents the actual smoothing parameter. When it is a vector, 'K-fold' cross validation is performed to select the ‘optimal’ lambda value and the model is fitted at such selected lambda value. To select the smoothing parameter via CV, foldid or nfolds may be supplied. If provided foldid overwrites nfolds, otherwise foldid is obtained via random extraction, namely sample(rep(seq(nfolds), length = n)). However selection of smoothing parameter is allowed only with a unique ps() term in the formula.

Value

This function returns an object of class gcrq, that is a list with the following components
coefficients  The matrix of estimated regression parameters; the number of columns equals the number of the fitted quantile curves.
x  the design matrix of the final fit (including the dummy rows used by penalty).
df  a vector reporting the df values for each quantile curve. See the section 'Warning' below.
rho  a vector including the values of the objective functions at the solution for each quantile curve.
fitted.values  a matrix of fitted quantiles (a column for each tau value)
residuals  a matrix of residuals (a column for each tau value)
D.matrix  the penalty matrix (multiplied by the smoothing parameter value).
D.matrix.nolambda  the penalty matrix.
plin  number of linear covariates in the model.
info.smooth  some information on the smoothing term (if included in the formula via ps).
BB  further information on the smoothing term (if present in the formula via ps),
including stuff useful for plotting via plot.gcrq().
Bderiv  if the smooth term is included, the first derivative of the B spline basis.
boot.coef  The array including the estimated coefficients at different bootstrap samples (provided that n.boot>0 has been set).
y  the response vector (if gcrq() has been called with y=TRUE).
contrasts  the contrasts used, when the model contains a factor.
xlevels  the levels of the factors (when included) used in fitting.
taus  a vector of values between 0 and 1 indicating the estimated quantile curves.
call  the matched call.

Warning

The function (and underlying method) works pretty well in obtaining point estimates and displaying quantile curves accordingly. Typically this is the main (and unique) goal when dealing with growth charts. However from a statistical viewpoint there are some important limitations affecting the theory and the relevant package,

1. Computation of model degrees of freedom

2. Computation of standard errors, currently implemented via the nonparametric (cases resampling) bootstrap (if n.boot>0)

Currently the function does not return standard errors for the parameter estimates (unless n.boot>0) and degrees of freedom are roughly computed by summing the ’zero’ residuals. Due to noncrossing constraints, the number of zero residuals might not be equal to the number of estimated parameters even in unpenalized models - except for the median, or for models where a single quantile curve has been fitted.
Note

This function is based upon the package quantreg by R. Koenker. Currently methods specific to the class "gcrq" are print.gcrq, summary.gcrq, vcov.gcrq, and plot.gcrq.

If the sample is not large, and/or the basis rank is large (i.e. a large number of columns) and/or there are relatively few distinct values in the covariate distribution, the fitting algorithm may fail returning error messages like the following

> Error info = 20 in stepy2: singular design

To remedy it, it suffices to change some arguments in ps(): to decrease ndx or deg (even by a small amount) or to increase (even by a small amount) the lambda value.

plot(m6, cv=TRUE) # display CV score versus lambda values
plot(m6, res=TRUE, grid=list(x=5, y=8)) # fitted curves at the best lambda value

## End(Not run)

growthData  Simulated data to illustrate capabilities of the package

Description

The `growthData` data frame has 200 rows and 3 columns.

Usage

data(growthData)

Format

A data frame with 200 observations on the following 3 variables.

- `x` the supposed ‘age’ variable.
- `y` the supposed growth variable (e.g. weight).
- `z` an additional variable to be considered in the model.

Details

Simulated data to illustrate capabilities of the package.

Examples

data(growthData)
with(growthData, plot(x,y))
ncross.rq.fitXB  
Estimation of noncrossing regression quantiles with monotonicity restrictions.

Description

These are internal functions of package quantregGrowth and should be not called by the user.

Usage

ncross.rq.fitXB(y, x, B = NULL, X = NULL, taus, interc=FALSE, monotone = FALSE, adj.middle = FALSE, ndx = 10, lambda = 0, deg = 3, dif = 3, eps = 1e-04, plott = 0, var.pen = NULL, ...)  
ncross.rq.fitX(y, X = NULL, taus, lambda = 0, adj.middle = FALSE, eps = 1e-04, ...)  
gcrq.rq.cv(y, B, X, taus, interc=FALSE, monotone, ndx, lambda, deg, dif, var.pen = NULL, cv = TRUE, nfolds = 10, foldid = NULL, eps = 1e-04)

Arguments

y  the responses vector. see gcrq  
x  the covariate supposed to have a nonlinear relationship.  
B  the B-spline basis.  
X  the design matrix for the linear parameters.  
taus  the percentiles of interest.  
interc  should the model intercept be estimated? see the same argument in gcrq  
monotone  numerical value (-1/0/+1) to define a non-increasing, unconstrained, and non-decreasing flexible fit, respectively.  
adj.middle  ignore it!  
ndx  number of internal intervals within the covariate range, see ps.  
lambda  smoothing parameter, see ps.  
deg  spline degree, see ps.  
dif  difference order of the spline coefficients in the penalty term.  
eps  tolerance value.  
plott  Plotting results, unuseful. See plot.gcrq.  
var.pen  Varying penalty, see ps.
foldid  vector (optional) to perform cross validation, see the same arguments in `gcrq`.
nfolds  number of folds for crossvalidation, see the same arguments in `gcrq`.
cv  returning cv scores; see the same arguments in `gcrq`.
...  optional.

Details
These functions are called by `gcrq` to fit growth charts based on regression quantiles with non-crossing and monotonicity restrictions. The computational methods are based on the package quantreg by R. Koenker and details are described in the reference paper.

Value
A list of fit information.

**plot.gcrq**

Plot method for gcrq objects

Description
Displaying the estimated growth charts from a gcrq fit.

Usage
```r
## S3 method for class 'gcrq'
plot(x, term, add = FALSE, res = FALSE, conf.level=0, legend = FALSE,
  select.tau, deriv = FALSE, cv = FALSE, transf=NULL, lambda0=FALSE,
  shade=FALSE, overlap=FALSE, rug=FALSE, n.points=100, grid=NULL, smoos=NULL, ...)
```
Arguments

x a fitted "gcrq" object.

term the smooth variable name entering the model via ps. Relevant fitted quantile curves will be plotted. It may be missing if the model includes a single smooth term.

add logical. If TRUE the fitted quantile curves are added on the current plot.

res logical. If TRUE 'partial' residuals are also displayed on the plot. Borrowing terminology from GLM, partial residuals for covariate $X_j$ are defined as fitted values corresponding to $X_j +$ residuals.
If there is a single covariate, the partial residuals correspond to observed data. If multiple quantile curves have been estimated, the fitted values coming from the 'middle' quantile curve are employed to compute the partial residuals. 'Middle' means 'corresponding to the $\tau_k$ closest to 0.50'. I don't know if that is the best choice.

conf.level logical. If larger than zero, pointwise confidence intervals for the fitted quantile curve are also shown (at the confidence level specified by conf.level).

legend logical. If TRUE a legend is drawn on the right side of the plot.

select.tau an optional numeric vector to draw only some of the fitted quantiles. Percentile values or integers 1 to length(tau) may be supplied.

deriv logical. If TRUE the first derivative of the curve is displayed.

cv logical. If TRUE and the "gcrq" object contains the matrix cv, then the cross-validation scores against the lambda values are plotted.

transf An optional character string (with "y" as argument) meaning a function to apply to the predicted values (and possibly residuals) before plotting. E.g. "(exp(y))" (default) it is taken as the inverse of function transf (*if* supplied in gcrq). See argument "transf" in gcrq(). If transf has been specified in gcrq(), use transf= "y" to force plotting on the transformed scale, i.e. without back transforming.

lambda0 logical. If cv=TRUE, should the CV plot include also the first CV value? Usually the first CV value is at lambda=0, and typically it is much bigger than the other values making the plot not easy to read. Default to FALSE not to display the first CV value in the plot.

shade logical. If TRUE and conf.level>0, the pointwise confidence intervals are portrayed via shaded areas.

overlap logical. If TRUE, and legend=TRUE, the legend crosses the fitted curve on the right side. Otherwise the legend is placed outside the fitted lines.

rug logical. If TRUE, the covariate distribution is displayed as a rug plot at the foot of the plot. Default to FALSE.

n.points numeric. Number of values used to plot the fitted curves. Large values provide smoother curves.

grid if provided, a grid of horizontal and vertical lines is drawn. grid has to be a list with the following components x,y,col,1ty,1wd. If x (y) is a vector, the vertical (horizontal) lines are drawn at these locations. If x (y) is a scalar, the vertical (horizontal) lines are drawn at x (y) equispaced values. col, 1ty,1wd refer to the lines to be drawn.
predict.gcrq

smoos logical, indicating if the residuals (provided that res=TRUE) will be drawn using a smoothed scatterplot. If NULL (default) the smoothed scatterplot will be employed when the number of observation is larger than 10000.

... Additional graphical parameters:
- xlab, ylab, ylim, and xlim (effective when add=FALSE);
- lwd, lty, and col for the fitted quantile lines; col<0 means color palette for the different curves;
- cex for the legend (if legend=TRUE);
- cex.p, col.p, and pch.p for the points (if res=TRUE).

Details
Takes a "gcrq" object and displays the fitted quantile curves. If conf.level>0 pointwise confidence intervals are also displayed. When the object contains the component cv, plot.gcrq can display cross-validation scores against the lambda values, see argument cv.

Value
The function simply generates a new plot or adds fitted curves to an existing one.

**predict.gcrq** Prediction for "gcrq" objects

**Description**
Takes a "gcrq" objects and computes fitted values

**Usage**
```r
## S3 method for class 'gcrq'
predict(object, newdata, se.fit=FALSE, transf=NULL, xreg, ...)
```
**predict.gcrq**

Arguments

- **object**: a fitted "gcrq" object.
- **newdata**: a dataframe including all the covariates of the model. The smooth term is represented by a covariate and proper basis functions will be build accordingly. If omitted, the fitted values are used. Ignored if **xreg** is provided.
- **se.fit**: logical. If TRUE, standard errors of the fitted quantiles are computed using the bootstrap covariance matrix.
- **transf**: An optional character string (with "y" as argument) meaning a function to apply to the predicted values. E.g. ";(\exp(y)-0.1)\". If NULL (default) it is taken as the inverse of function **transf** (*if* supplied in **gcrq**. The standard errors (provided se.fit=TRUE has been set) are adjusted accordingly via the Delta method. See argument "transf" in **gcrq**(). If **transf** has been specified in **gcrq**(), use transf="y" to force predictions on the transformed scale, i.e. without back transforming.
- **xreg**: the design matrix for which predictions are requested. Note **xreg** has to include the basis functions of the B-spline.
- ... arguments passed to other functions

Details

**predict.gcrq** computes fitted quantiles as a function of observations included in **newdata** or **xreg**. Either **newdata** or **xreg** have to be supplied, but **newdata** is ignored when **xreg** is provided.

Value

If se.fit=FALSE, a matrix of fitted values with number of rows equal to number of rows of input data and number of columns depending on the number of fitted quantile curves (i.e length of taus).
If se=TRUE, a list of matrices (fitted values and standard errors).

Note

This function is at a preliminary stage and it should be replaced by the method **predict.gcrq**. Please use it with care. This function is not expect to work if the fitted model includes factors or terms like **poly**().

`summary.gcrq`

ps  

Specifying a smooth term in the gcrq formula.

Description

Function used to define the smooth term (via P-splines) within the gcrq formula. The function actually does not evaluate a (spline) smooth, but simply it passes relevant information to proper fitter functions.

Usage

```r
ps(x, monotone = 0, lambda = 0, d = 3, ndx = NULL, deg = 3, 
   var.pen = NULL)
```
Arguments

- **x**: The quantitative covariate supposed to have a nonlinear relationship with the quantiles. In growth charts, this variable is typically the age.
- **monotone**: Numeric value to set up monotonicity restrictions on the fitted smooth function
  - '0' = no constrain;
  - '1' = non decreasing smooth function;
  - '-1' = non increasing smooth function.
- **lambda**: A supplied smoothing parameter for the smooth term. If it is a vector, cross validation is performed to select the ‘best’ value.
- **d**: The difference order of the penalty. Default to 3.
- **ndx**: The number of intervals of the covariate range used to build the B-spline basis. Non-integer values are rounded by `round()`. If `NULL`, default, the empirical rule of Ruppert is used, namely \( \min(n/4, 40) \). It could be reduced (but no less than 10, say) if the sample size is not large, and the default value leads to some error in the fitting procedure, see section `Note` in `gcrq`.
- **deg**: The degree of the spline polynomial. Default to 3.
- **var.pen**: A character indicating the varying penalty. See Details.

Details

When `lambda`=0 an unpenalized fit is obtained. At ‘middle’ lambda values, the fitted curve is a piecewise polynomial of order \( d-1 \). The fit gets smoother as lambda increases, and for a very large value of lambda, it approaches to a polynomial of degree \( d-1 \). It is also possible to put a varying penalty to set a different amount of smoothing. Namely for a constant smoothing (\( \text{var.pen}=\text{NULL} \)) the penalty is \( \lambda \sum_{k} |\Delta_{d}^{k}| \) where \( \Delta_{d}^{k} \) is the k-th difference (of order \( d \)) of the spline coefficients. For instance if \( d = 1 \), \( |\Delta_{1}^{k}| = |b_{k} - b_{k-1}| \) where the \( b_{k} \) are the spline coefficients. When a varying penalty is set, the penalty becomes \( \lambda \sum_{k} |\Delta_{d}^{k}|w_{k} \). The weights \( w_{k} \) depend on `var.pen`; for instance `var.pen="((1:k)^2)"` results in \( w_{k} = k^2 \). See model m5 in examples of `gcrq`.

Value

The function simply returns the covariate with added attributes relevant to smooth term.

Examples

## see ?gcrq
**Variance-Covariance Matrix for a Fitted 'cgrq' Model**

**Description**

Returns the (currently only bootstrap-based) variance-covariance matrix of the parameter estimates of a fitted gcrq model object.

**Usage**

```r
## S3 method for class 'gcrq'
vcov(object, term, ...)```

**Arguments**

- `object`: a fitted model object of class "gcrq" returned by `gcrq()`.
- `term`: if specified the returned covariance matrix includes entries relevant to parameter estimates for that 'term' only. If missing, the returned matrices refer to all model parameter estimates.
- `...`: additional arguments.

**Details**

If the "gcrq" object includes results from bootstrap runs (namely the component `boot.coef` is not `NULL`), `vcov.gcrq()` computes the covariance matrix for the parameter estimates of each quantile curve. If not, 100 bootstrap replicates are run.

**Value**

A list including the covariance matrices of the parameter estimates for each regression quantile curve.
