rCMA-package

R interface to the Java CMA-ES of Niko Hansen

Description

CMA-ES R-to-Java interface

Details

| Package:  | rCMA               |
| Type:     | Package            |
| Version:  | 1.1                |
| Date:     | 2015-04-30         |
| License:  | GPL (>= 3)         |
| LazyLoad: | yes                |

rCMA is a package to perform CMA-ES optimization, using the *Java* implementation by Niko Hansen [Hansen2009].

CMA-ES [HansOst96, Hansen13] is the Covariance Matrix Adapting Evolutionary Strategy for numeric black box optimization. The main features of rCMA are:

1. Ability to start the Java CMA-ES optimization with fitness functions defined in R.
2. Constraint handling: Arbitrary constraints can be incorporated, see function parameter isFeasible in cmaOptimDP.
3. Extensibility: Full access to all methods of the Java class CMAEvolutionStrategy through package rJava. New methods can be added easily. See the documentation of cmaEvalMeanX for further details, explanation of JNI types and a full example.
4. Test and Debug: The access of Java methods from R allows for easy debugging and test of programs using CMAEvolutionStrategy through R scripts without the necessity to change the underlying JAR file.

The main entry point functions are cmaNew, cmaInit and cmaOptimDP.

Note: To install rJava properly on some Unix systems, it might be necessary to issue as root the command R CMD javareconf once, or, as normal user to issue the command R CMD javareconf -e prior to installing package rJava or prior to loading library rJava.

cmaCalcFitness

cmaCalcFitness Calculate the fitness of a population.

Description
The population is usually obtained by cmaSamplePopulation.

Usage
cmaCalcFitness(cma, popR, fitFunc)

Arguments
- cma: CMA-ES Java object, already initialized with cmaInit
- popR: a (dimension x popSize) matrix from cmaSamplePopulation
- fitFunc: a function to be minimized. Signature: accepts a vector x, returns a double.

Value
fitness, a vector of length cmaGetPopulationSize(cma) with the fitness of each individuum

Author(s)
Wolfgang Konen, FHK, 2013

See Also
cmaSamplePopulation, cmaUpdateDistribution, cmaNew

Examples
cma <- cmaNew();
cmaInit(cma, dimension=2, initialX=1.5);
popR <- cmaSamplePopulation(cma);
fitFunc <- function(x) {sum(x*x)};
fitness <- cmaCalcFitness(cma, popR, fitFunc);
cmaUpdateDistribution(cma, fitness);
cmaEvalMeanX

Evaluate the meanX of the current population.

Description

After executing cmaOptimDP, there is a current population and a best-ever solution. Evaluate for the mean of the current population whether it is feasible and whether the mean is an even better solution. If so, update the best-ever solution.

Usage

cmaEvalMeanX(cma, fitFunc, isFeasible = function(x) TRUE)

Arguments

cma CMA-ES Java object, already initialized with cmaInit
fitFunc a function to be minimized. Signature: accepts a vector x, returns a double.
isFeasible [function(x){TRUE}] a Boolean function checking the feasibility of the vector x. The default is to return always TRUE.

Details

The code of this function is also instructive as a full example for the extensibility of the rJava interface to CMA-ES. See the full code in demo/demoEvalMeanX. Some example rJava-calls are:

```r
rJava::.jcall(cma,"[D","getMeanX");
betweenObj =
rJava::.jcall(cma,"Ljava/nira/optimization/cmaes/CMASolution;","setFitnessOfMeanX",fitFunc(meanX,result));
rJava::.jcall(betweenObj,"J","getEvaluationNumber");
```

Every direct method of classes in the CMA-ES Java package cmaes (see [Hansen09] for the complete javadoc and [Hansen13] for an overview on CMA-ES in total) can be accessed with the .jcall-mechanism of the rJava R package:

```r
rJava::.jcall(obj,returnType,method,...)
```

where ... stands for the calling parameter(s) of method.
returnType is a string following the JNI type convention (see, e.g. [Oracle14])

<table>
<thead>
<tr>
<th>Field Descriptor</th>
<th>Java Language Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Z</td>
<td>boolean</td>
</tr>
<tr>
<td>C</td>
<td>char</td>
</tr>
<tr>
<td>I</td>
<td>int</td>
</tr>
<tr>
<td>J</td>
<td>long</td>
</tr>
<tr>
<td>F</td>
<td>float</td>
</tr>
<tr>
<td>D</td>
<td>double</td>
</tr>
<tr>
<td>[I</td>
<td>int[]</td>
</tr>
</tbody>
</table>
(Note: (a) the terminating ";" in "Ljava/langString;" (l) and (b) "S" is a short hand for "Ljava/langString;" and "T" is the re-mapped code for short.)

The calling parameters in ... have to be matched exactly. In R, numeric vectors are stored as doubles, so the calling syntax

```r
bestSolutionObj = .jcall(cmaLrtypeL"setfitnessOfMeanX",fitFunc(meanX));
```

is just right for the Java method `setFitnessOfMeanX(double[])`. In other cases, the calling R variable `x` has to be cast explicitly:

<table>
<thead>
<tr>
<th>Cast</th>
<th>Java Language Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>.jbyte(x)</td>
<td>byte</td>
</tr>
<tr>
<td>.jchar(x)</td>
<td>char</td>
</tr>
<tr>
<td>as.integer(x)</td>
<td>int</td>
</tr>
<tr>
<td>.jlong(x)</td>
<td>long</td>
</tr>
<tr>
<td>.jfloat(x)</td>
<td>float</td>
</tr>
</tbody>
</table>

**Value**

`bestSolution`, a list with entries:

- **bestX** a vector of length dimension containing the best-ever solution, including `meanX`
- **meanX** a vector of length dimension containing the mean of the current (last) population in `cma`
- **bestFitness** the best-ever fitness value, including the evaluation of `meanX`
- **bestEvalNum** the function evaluation count where `bestFitness` occured
- **lastEvalNum** the total function evaluation count. If `bestEvalNum==lastEvalNum` then the best-ever fitness occured in the evaluation of `meanX`.

cmaInit, cmaOptimDP

Examples

```r
## Not run:
## just to show the syntax, without calling cmaOptimDP
fitFunc <- function(x) { sum(x**x); }
isFeasible <- function(x) { TRUE; }
cma <- cmaNew(propFile="CMAEvolutionStrategy.properties");
cmaInit(cma,dimension=2,initialX=1.5);
bestSolution=cmaEvalMeanX(cma,fitFunc,isFeasible);
str(bestsolution);
```

---

cmaInit

*Initialize a CMA-ES Java object.*

**Description**

Initialize a CMA-ES Java object.

**Usage**

```r
cmaInit(cma, seed = NULL, dimension = NULL, initialX = NULL,
        initialStandardDeviations = NULL)
```

**Arguments**

- **cma**: CMA-ES Java object, as created by `cmaNew`
- **seed**: [NULL] if not NULL, set the seed to the given value
- **dimension**: [NULL] if not NULL, overwrite the dimension setting from `propFile` (`cmaNew`) initialX: [NULL] if not NULL, overwrite the initialX setting from `propFile` (`cmaNew`). initialX can be a double or a double vector of length `dimension`
- **initialStandardDeviations**: [NULL] if not NULL, overwrite the initialStandardDeviations setting from `propFile` `cmaNew`. initialStandardDeviations can be a double or a double vector of length `dimension`

**Value**

fitness, a vector of 0’s with the length of the intended population.
cmaNew

Note
As a side effect, the CMA-ES Java object cma of class CMAEvolutionStrategy is transferred into an augmented state. As a second side effect, the population size is set to

$$\lambda = 4 + 3 \lfloor \ln(n) \rfloor$$

where $n =$ dimension.

Author(s)
Wolfgang Konen, FHK, 2013

See Also
cmaNew, cmaOptimDP

Examples
```r
cma <- cmaNew();
cmaInit(cma, seed=42, dimension=2, initialX=1.5);
```

---

**Description**
Create a new CMA-ES Java object.

**Usage**
cmaNew(propFile = NULL)

**Arguments**
- **propFile** [NULL] filename of a file with property settings. If NULL, read file CMAEvolutionStrategy.properties from the package directory (find.package("rCMA"))

**Value**
the new CMA-ES Java object of class CMAEvolutionStrategy, which has as additional attribute props, the Java Properties object as read from propFile.

**Note**
The default properties file can be found in CMAEvolutionStrategy.properties. A read-only copy can be inspected by browsing to "Index" (of package rCMA), then "Overview of user guides ...". It allows to set more parameter, especially more stop conditions.
Perform a CMA-ES optimization with constraints (DP).

Description

The optimization uses DP (death penalty) for handling constraint violations: Each time an infeasible individual is encountered, it is thrown away and a new individual is resampled from the CMA distribution.

Usage

cmaOptimDP(cma, fitFunc, isFeasible = function(x) { TRUE },
        maxDimPrint = 5, iterPrint = 10, verbose = 2)

Arguments

cma  CMA-ES Java object, already initialized with cmainit
fitFunc  a function to be minimized. Signature: accepts a vector x, returns a double.
isFeasible  [function(x){TRUE}] a Boolean function checking the feasibility of the vector x. The default is to return always TRUE.
maxDimPrint  [5] how many dimensions of vector x to print in diagnostic output
iterPrint  [10] after how many iterations should diagnostic output be printed?
verbose  [2] possible values are 0 (no output), 1, 2 (much output)
Details

This function loops through iterations (generations) until a stop condition is met: In each iteration, a population is sampled (infeasible individuals are replaced via Java function resampleSingle), its fitness vector is evaluated and the CMA distribution is updated according to this fitness vector. Every iterPrint generations a one-line diagnostic output of the form

\[
\text{iter } \text{fitness } | \ x_1 \ x_2 \ \ldots \ x_p
\]

is printed where fitness is the current best value of the fitness function to be minimized and \( x_1 \ x_2 \ \ldots \ x_p \) are the first maxDimPrint dimensions of the corresponding best point in input space.

Value

res, a list with diagnostic output from the optimization run:

- sMsg: a string vector with all console output from the optimization run. To print it, use: cat(sMsg) or for (x in sMsg) cat(x)
- bestX: vector of length dimension with the best-ever solution X
- bestFitness: the corresponding best-ever fitness
- bestEvalNum: the fitness function evaluation number which gave this best-ever result
- nIter: number of iterations
- fitnessVec: vector of length nIter: the best fitness after each iteration
- xMat: \((nIter \times \text{dimension})\)-matrix: \(xMat[i,]\) is the best solution \(X\) after iteration \(i\)
- cfe: number of constraint function evaluations (isFeasible)
- ffe: number of fitness function evaluations (fitFunc)

Note

If your fitness function depends on other parameters besides \(x\), then encapsulate it in a new function fitFunc at a place where the other parameters are accessible and rely on R’s mechanism to locate the other parameters in the environment surrounding fitFunc:

\[
\text{par1 } \leftarrow \text{someObject};
\]

\[
\text{fitFunc } \leftarrow \text{function(x) \{ myFuncWithOtherPars(x,par1); \}}
\]

cmaNew, cmaInit
Examples

```r
library(rCMA)
fitfunc <- function(x) { sum(x**2); }
isfeasible <- function(x) { (sum(x) - length(x)) >= 0; }
n = 2;

cma <- cmaNew(propfile="CMAEvolutionStrategy.properties");
cmaInit(cma, seed=42, dimension=n, initialX=1.5, initialStandardDeviations=0.2);
res1 <- cmaOptimDP(cma, fitfunc, iterPrint=30);

cma <- cmaNew(propfile="CMAEvolutionStrategy.properties");
cmaInit(cma, seed=42, dimension=n, initialX=1.5, initialStandardDeviations=0.2);
res2 <- cmaOptimDP(cma, fitfunc, isfeasible, iterPrint=30);

ftarget <- c(0, n);
plot(res1$fitnessVec-ftarget[1], type="l", log="y", xlab="Iteration", ylab="Distance to target fitness");
lines(res2$fitnessVec-ftarget[2], col="red");
legend("topright", legend=c("TR2","sphere"), lwd=rep(1,2), col=c("red","black"))

cma::cmaEvalMeanX(cma, fitfunc, isfeasible);
```

Sample a population from the current CMA-ES distribution.
cmaSetDimension

Description

The population size is given by `cmaGetPopulationSize(cma)`. It can be either set manually with `cmaSetPopulationSize(cma,p)`, prior to `cmaInit(cma)`, or CMA-ES will use the default population size

\[ \text{popSize} = 4 + 3 \times \log(\text{dimension}). \]

Usage

`cmaSamplePopulation(cma)`

Arguments

- `cma` CMA-ES Java object, already initialized with `cmaInit`

Value

`popR`, a `(dimension \times \text{popSize})` matrix with `popR[:,1]` being the first individual in the population.

\[ \text{dimension} = \text{cmaGetDimension(cma)} \]
\[ \text{popSize} = \text{cmaGetPopulationSize(cma)} \]

Author(s)

Wolfgang Konen, FHK, 2013

See Also

`cmaUpdateDistribution`, `cmaNew`

Examples

```r
  cma <- cmaNew();
  cmaInit(cma, dimension=2, initialX=1.5);
  popR <- cmaSamplePopulation(cma);
```

---

description

Get or set various elements of CMA-ES Java object `cma`.

- `cmaSetDimension` sets the problem dimension (only prior to `cmaInit`)
- `cmaGetDimension` returns the problem dimension
- `cmaSetPopulationSize` sets the population size (only prior to `cmaInit`)
- `cmaGetPopulationSize` returns the population size
- `cmaSetInitialX` set the mean vector for the initial population (only prior to `cmaInit`)
cmaGetInitialX returns the mean vector for the initial population
cmaSetCountEval sets the counter for fitness function evaluations (only prior to cmaInit)
cmaGetCountEval returns the counter for fitness function evaluations

Usage

cmaSetDimension(cma, i)
cmaGetDimension(cma)
cmaSetPopulationSize(cma, i)
cmaGetPopulationSize(cma)
cmaSetInitialX(cma, initialX)
cmaGetInitialX(cma)
cmaSetCountEval(cma, p)
cmaGetCountEval(cma)

Arguments

cma CMA-ES Java object, created with cmaNew
i a parameter of type integer
initialX either a double or a double vector of length cmaGetDimension
p a parameter of type long

Value

none for the setters, the requested element(s) for the getters

See Also

cmaSetStopFitness, cmaNew, cmaInit

Description

Set various stop conditions of CMA-ES Java object cma (only prior to cmaInit).

cmaSetStopFitness sets the stop condition: fitness function below d (default: DOUBLE.MinValue)
cmaSetStopMaxFunEvals sets the stop condition: max number of fitness function evaluations

cmaSetStopTolFun sets the stop condition: delta of fitness function below d (default: 1e-12)
cmaUpdateDistribution

Usage

cmaSetStopFitness(cma, d)
cmaSetStopMaxFunEvals(cma, p)
cmaSetStopTolFun(cma, d)

Arguments

cma CMA-ES Java object, created with cmaNew
d a parameter of type double
p a parameter of type long

Note

If your fitness can become negative, you need to set cmaSetStopFitness to a value different from
the default to prevent premature stopping.

The properties file (read by cmaNew) can be used to set further stop conditions. If they are not set,
the following defaults are active:

<table>
<thead>
<tr>
<th>name</th>
<th>default setting</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>stopTolFunHist</td>
<td>1e-13</td>
<td>similar to stopTolFun, see CMA-ES Javadoc for details</td>
</tr>
<tr>
<td>stopTolX</td>
<td>0.0</td>
<td>stop if search steps become smaller than stopTolX</td>
</tr>
<tr>
<td>stopTolXfactor</td>
<td>0.0</td>
<td>stop if search steps become smaller than stopTolXFactor * initial step size</td>
</tr>
<tr>
<td>stopMaxIter</td>
<td>+Inf</td>
<td>stop if number of iterations (generations) are greater</td>
</tr>
</tbody>
</table>

See Also

cmaSetDimension, cmaNew, cmaInit

cmaUpdateDistribution Update CMA-ES distribution with the fitness vector of the last population.

Description

Update CMA-ES distribution with the fitness vector of the last population.

Usage

cmaUpdateDistribution(cma, fitness)

Arguments

cma CMA-ES Java object, already initialized with cmaInit
fitness vector of length cmaGetPopulationSize(cma) with the fitness of each individual
Note

As a side effect, the CMA-ES Java object cma of class CMAEvolutionStrategy is augmented.
