Package ‘rpart.plot’

April 21, 2017

Version 2.1.2

Title Plot ‘rpart’ Models: An Enhanced Version of ‘plot.rpart’

Author Stephen Milborrow

Maintainer Stephen Milborrow <milbo@sonic.net>

Depends R (>= 3.2.0), rpart (>= 4.1-10)

Suggests earth (>= 4.4.6)

Description Plot ‘rpart’ models. Extends plot.rpart() and text.rpart() in the ‘rpart’ package.

Index 23
**Description**

Plot an `rpart` model.

This function combines and extends `plot.rpart` and `text.rpart` in the `rpart` package. For an overview, please see the package vignette *Plotting rpart trees with the rpart.plot package*.

The function `rpart.plot` provides a simplified interface to this function. First-time users should use `rpart.plot` rather than this function.

The arguments of this function are a superset of those of `rpart.plot` and some of the arguments have different defaults. See the `rpart.plot` help page for a table showing the different defaults.

(The defaults are different for historical reasons: for backwards compatibility the defaults of `prp` haven’t changed, whereas the defaults of `rpart.plot` were changed when `type="auto"` and `box.palette` were introduced in version 2.0.0 of this package.)

**Usage**

```
prp(x=stop("no 'x' arg"),
  type=0, extra=0, under=FALSE, clip.rightlabs=TRUE,
  nn=FALSE, ni=FALSE, yesno=TRUE,
  fallen.leaves=FALSE, branch=if(fallen.leaves) 1 else .2,
  uniform=TRUE, left=TRUE, xflip=FALSE, yflip=FALSE,
  Margin=0, space=1, gap=NULL,
  digits=2, varlen=8, faclen=3,
  cex=NULL, tweak=1,
  compress=TRUE, ycompress=uniform,
  trace=FALSE, snip=FALSE, snip.fun=NULL,
  box.col=0, box.palette=0,
  pal.thresh=NULL, pal.node.fun=FALSE,
  border.col=col,
  round=NULL, leaf.round=NULL,
  shadow.col=0, prefix="", suffix="", xsep=NULL,
  under.font=font, under.col=1, under.cex=.8,
  split.cex=1, split.font=2, split.family=family, split.col=1,
  split.box.col=0, split.border.col=0,
  split.lty=1, split.lwd=FALSE, split.round=0,
  split.shadow.col=0,
  split.prefix="", right.split.prefix=NULL,
  split.suffix="", right.split.suffix=NULL,
  facsep="", eq=" = ", lt=" < ", ge=" >= ",
)```

```
Arguments

**x**  
An `rpart` object. The only required argument.

**type**  
Type of plot. Possible values:

- **0** Default. Draw a split label at each split and a node label at each leaf.
- **1** Label all nodes, not just leaves. Similar to `text.rpart`'s *all*=T.
- **2** Like 1 but draw the split labels below the node labels. Similar to the plots in the CART book.
- **3** Draw separate split labels for the left and right directions.
- **4** Like 3 but label all nodes, not just leaves. Similar to `text.rpart`'s *fancy*=T. See also `clip.right.labs`.

**extra**  
Display extra information at the nodes. Possible values:

"auto" (case insensitive)  
Automatically select a value based on the model type, as follows:

- `extra=106` class model with a binary response
- `extra=104` class model with a response having more than two levels
- `extra=100` other models
Default. No extra information.

1 Display the number of observations that fall in the node (per class for class objects; prefixed by the number of events for poisson and exp models). Similar to text.rpart's use.n=TRUE.

2 Class models: display the classification rate at the node, expressed as the number of correct classifications and the number of observations in the node. Poisson and exp models: display the number of events.

3 Class models: misclassification rate at the node, expressed as the number of incorrect classifications and the number of observations in the node.

4 Class models: probability per class of observations in the node (conditioned on the node, sum across a node is 1).

5 Class models: like 4 but do not display the fitted class.

6 Class models: the probability of the second class only. Useful for binary responses.

7 Class models: like 6 but do not display the fitted class.

8 Class models: the probability of the fitted class.

9 Class models: the probabilities times the fraction of observations in the node (the probability relative to all observations, sum across all leaves is 1).

+100 Add 100 to any of the above to also display the percentage of observations in the node. For example extra=101 displays the number and percentage of observations in the node. Actually, it's a weighted percentage using the weights passed to rpart.

Note 1: Unlike text.rpart, by default prp uses its own routine for generating node labels (not the function attached to the object). See the node.fun argument.

Note 2: The extra argument has special meaning for mpart objects. See the Appendix to this package's vignette.

under Applies only if extra > 0. Default FALSE, meaning put the extra text \textit{in} the box. Use TRUE to put the text \textit{under} the box. See also \textit{under\textperiodcentered cex}.

clip.right.labs Default is TRUE meaning “clip” the right-hand split labels, i.e. do not print \texttt{variable=}. Applies only if \texttt{type}=3 or 4. See also \textit{clip.left.labs}.

nn Display the node numbers. Default FALSE. (In the current implementation some overplotting may occur with \texttt{nn=TRUE}.)

ni Display the node indices, i.e. the row numbers of the nodes in the object's frame. Default FALSE.

yesno One of

0 don't write \texttt{yes} and \texttt{no} on the tree
1 (default) write \texttt{yes} and \texttt{no} at the top split
2 write \texttt{yes} and \texttt{no} at all splits. Seems to work best with fallen.leaves=TRUE, split.border.col=1. (The yesno argument is ignored if \texttt{type}=3 or 4. Use \texttt{nn.col} and the other \texttt{nn} parameters to change the color etc. of the \texttt{yes} and \texttt{no} text. Use \texttt{yes.text} and \texttt{no.text} to change the actual text displayed.)

fallen.leaves Default FALSE. If TRUE, position the leaf nodes at the bottom of the graph.
branch
Controls the shape of the branch lines. Specify a value between 0 (V shaped branches) and 1 (square shouldered branches). Default is if(fallen.leaves) 1 else .2.

uniform
If TRUE (the default), the vertical spacing of the nodes is uniform. If FALSE, the nodes are spaced proportionally to the fit (more precisely, to the difference between a node’s deviance and the sum of its two children’s deviances). Very small vertical spaces are automatically artificially expanded to make room for the labels, see minbranch. Note: uniform=FALSE with cex=NULL (the default) can sometimes cause very small text.

left
Default TRUE, meaning the left side of a split is the path taken if the split condition is true. With left=FALSE the split labels are changed so the right side is true.

xflip
Default FALSE. If TRUE, flip the tree horizontally.

yflip
Default FALSE. If TRUE, flip the tree vertically, so the root is at the bottom.

Margin
Extra white space around the tree, as a fraction of the graph width. Default 0, meaning no extra space. To add say 10% space around the tree use Margin=0.1. (This is the margin argument of plot.rpart. The name was changed to prevent partial matching with mar, which can be passed in as a ...argument.)

gap
Minimum horizontal gap between the (possibly invisible) boxes, in character widths. Default NULL, meaning automatically choose a suitable value (normally 1, but if the graph is very crowded will be set to 0, permitting boxes to touch to allow a bigger cex). See also space.

digits
The number of significant digits in displayed numbers. Default 2. If 0, use getOption("digits"). If negative, use the standard format function (with the absolute value of digits).

When digits is positive, the following details apply:
Numbers from 0.001 to 9999 are printed without an exponent (and the number of digits is actually only a suggestion, see format for details). Numbers out that range are printed with an “engineering” exponent (a multiple of 3).

varlen
Length of variable names in text at the splits (and, for class responses, the class in the node label). Default -8, meaning truncate to eight characters. Possible values:

0 use full names.

greater than 0 call abbreviate with the given varlen.

less than 0 truncate variable names to the shortest length where they are still unique, but never truncate to shorter than abs(varlen).

faclen
Length of factor level names in splits. Default 3, meaning abbreviate to three characters. Possible values are as varlen above, except that for back-compatibility with text.rpart the special value 1 means represent the factor levels with alphabetic characters (a for the first level, b for the second, etc.).
cex
Default NULL, meaning calculate the text size automatically.

tweak
Adjust the (possibly automatically calculated) cex. Default 1, meaning no adjustment. Use say `tweak=1.2` to make the text 20% larger. However, since font sizes are discrete the cex you ask for may not be exactly the cex you get. And a small change to tweak may not actually change the type size, or change it more than you want.

compress
If TRUE (the default), make more space by shifting nodes horizontally where space is available. This often allows larger text. (This is the same as `plot.rpart`'s argument of the same name, except that here the default is TRUE.)

ycompress
If TRUE (the default unless `uniform=FALSE`), make more space by shifting labels vertically where space is available. Actually, this only kicks in if the initial automatically calculated cex is less than 0.7. Use `ycompress=FALSE` if you feel the resulting display is too messy. In the current implementation, the shifting algorithm works a little better (allowing larger text) with `type=1, 2, or 3`.

trace
Default FALSE. Use TRUE to print the automatically calculated cex, xlim, and ylim. Use integer values greater than 1 for more detailed tracing.

snip
Default FALSE. Set TRUE to interactively trim the tree with the mouse. See the package vignette (or just try it).

snip.fun
Function invoked after each mouse click when snip=TRUE. Default NULL, meaning no function. Otherwise set snip.fun to your own function with the prototype `function(tree)`, where tree is the snipped tree. See the package vignette for an example.

The following control the node labels.

box.col
Color of the boxes around the text. Default 0, meaning use the background color. If this argument is used, the box.palette argument is ignored.

box.palette
Palette for coloring the node boxes based on the fitted value. This is a vector of colors, for example `box.palette=c("green", "green2", "green4")`. Small fitted values are displayed with colors at the start of the vector; large values with colors at the end.

The special value `box.palette=0` (default for prp) uses the background color (typically white).

The special value `box.palette="auto"` (default for rpart.plot, case insensitive) automatically selects a predefined palette based on the type of model.

Otherwise specify a predefined palette e.g. `box.palette="Grays"` for the predefined gray palette (a range of grays). The predefined palettes are (see the `show.prp.palettes` function):

- Grays
- Greys
- Greens
- Blues
- Browns
- Oranges
- Reds
- Purples
- Gy
- Gn
- Bu
- Bn
- Or
- Rd
- Pu
- (alternative names for the above palettes)
- BuGn
- GnRd
- BuOr etc. (two-color diverging palettes: any combination of two of the above palettes)
- Rd1Gn
- GnY1Rd
- BlGnY1
- Y1GnBl (three color palettes)

Prefix the palette name with "-" to reverse the order of the colors e.g. `box.palette="-auto"` or `box.palette="-Grays"`.

The box.palette argument is ignored if the box.col palette argument is specified.
pal.thresh Applies when box.palette is a two-color diverging palette (such as BuGn).
Specifies the response threshold to split the two sub-palettes (such as Bu and Gn).
For example, to display fitted values less than 90 in shades of blue and values greater than 90 in shades of green, use pal.thresh=90 with box.palette="BuGn".
By default pal.thresh is calculated automatically. (For a two-class response the default threshold is 0.5; for a continuous response the default is the median fitted value.)

Node boxes for fitted values less than the threshold are displayed using colors from the first sub-palette; boxes for fitted values greater than the threshold are displayed using colors from the second sub-palette.
This argument is ignored if box.palette isn’t a two-color diverging palette, and is ignored for models with multiple-class responses (more than two classes).

pal.node.fun Specifies how the box.palette argument is handled when the node.fun argument is specified.
Default is FALSE, meaning ignore node.fun and use the fitted value to select the node color from box.palette as usual.
If TRUE, use the label returned by the node function (instead of the fitted value) to select the color. The first number in each label returned by the node function is used, skipping over any non-numeric initial text in the label. An error message will be issued if a label doesn’t include a number.
This argument is ignored if node.fun isn’t specified, and is ignored for models with multiple-class responses (more than two classes).

border.col Color of the box border around the text. Default col, the color of the text in the box. Use 0 for no border. (Note: par settings like col can be passed in as ...arguments. If not passed in, par("col") is used.)

round Controls the rounding of the corners of the node boxes. Default NULL, meaning calculate automatically. Else specify 0 for sharp edges, and values greater than 0 for rounded edges. Bigger is more round. Values too big for the size of the box get silently reduced.

leaf.round Controls the rounding of the corners of the leaf node boxes. Default NULL, meaning use round. Else specify a value greater than or equal to 0.

shadow.col Color of the shadow under the boxes. Default 0, no shadow. Try "gray" or "darkgray". (Note: overlapping shadows look better on devices that support alpha channels. If you get the message "Warning: semi-transparency is not supported" please let me know – it means that a fix is needed to the code that determines if the device supports alpha channels.)

prefix Default ".". Prepend this string to the node labels. So could be the name of the fitted response, for instance.

suffix Default ".". Append this string to the node labels. Text after a double newline "\n\n" (if any) will be plotted under the box. (Actually, double newlines can be used in any of the prefix or suffix arguments for this purpose.)

xsep String which separates the individual counts and probabilities in node labels when extra>0. Default NULL meaning automatically select: usually "\t" (two spaces), but "/" for rates. Use xsep="/" for compatibility with
The following control the text under the boxes (apply only if under=TRUE or there is a double newline 
\n\n in prefix or suffix).

- **under.font**: Font of the text under the box. Default font (which can be passed in as a ...argument).
- **under.col**: Color of the text under the box. Default 1.
- **under.cex**: Size of the text under the box relative to the text in the box. Default .8, smaller than the text in the box.

The following control the split labels.

- **split.cex**: Size of the split text relative to cex (which by default is calculated automatically). Default 1.
- **split.font**: Font for the split labels. Default 2, bold. (Note: use font to change the node label text.)
- **split.family**: Font family for the split labels. Default "", or use something like split.family="serif". (Note: use family to change the node label text.)
- **split.col**: Color of the split label text. Default 1. (Note: use col to change the node label text.)
- **split.box.col**: Color of the split boxes. Default \( \emptyset \), meaning use the background color.
- **split.border.col**: Color of the split box borders. Default \( \emptyset \), invisible.
- **split.lty**: Line type for the split box borders. The default is 1, but the border will be invisible unless you change the default split.border.col. (Note: use lty to change the node box borders.)
- **split.lwd**: Line width of the split box border relative to cex (which by default is calculated automatically). The border is by default invisible, see codesplit.border.col.
- **split.round**: Controls the rounding of the corners of the split boxes. Default \( \emptyset \), meaning sharp corners. Else specify a value greater than or equal to 0. The split boxes are by default invisible, see split.box.col and split.border.col.
- **split.shadow.col**: Color of the shadow under the split boxes. Default \( \emptyset \), no shadow.
- **split.prefix**: Default "". Prepend this string to the split labels.
- **right.split.prefix**: Default split.prefix. Prepend this string to the right split labels. Applies only when type=3 or 4.
- **split.suffix**: Default "". Append this string to the split labels.
- **right.split.suffix**: Default split.suffix. Append this string to the right split labels. Applies only when type=3 or 4.
- **facsep**: Default ",\,". String which separates the factor levels in split labels. See also xsep, which separates the individual counts when extra is used.
eq

Default " = ". String which separates the factor name from the levels in split labels. The idea is that you can add or remove spaces around the =, or use words if that suits you.

lt

Default " < ". String which represents “less than” in split labels.

ge

Default " >= ". String which represents “greater than or equal” in split labels.

**The following control the branches.**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>branch.col</td>
<td>Color of the branch lines. Default 1, but set to &quot;gray&quot; if branch.type is nonzero.</td>
</tr>
<tr>
<td>branch.lty</td>
<td>Branch line type. Default 1.</td>
</tr>
<tr>
<td>branch.lwd</td>
<td>Line width of the branch lines relative to cex (which by default is calculated automatically). (Note: branch.lwd does not control the width of the “wide branches” drawn when branch.type is nonzero.)</td>
</tr>
<tr>
<td>branch.type</td>
<td>Default 0. If nonzero draw “wide branches”, with branch widths proportional to the parameter selected by branch.type as follows: 0 The default. The branch lines are drawn conventionally. 1 deviance 2 sqrt(deviance) 3 deviance / nobs 4 sqrt(deviance / nobs) (the standard deviation when method=&quot;anova&quot;) 5 weight (frame$wt). This is the number of observations at the node, unless rpart’s weight argument was used. 6 complexity 7 abs(predicted value) 8 predicted value - min(predicted value) 9 constant (for checking visual perception of the relative width of branches).</td>
</tr>
</tbody>
</table>

Otherwise set branch.type to your own function. The function should take a single argument x (the rpart object) and return a numeric vector of non-negative widths corresponding to rows in frame. See get.branch.widths in the source code. 

Note: with a nonzero branch.type, in the current implementation the branch argument will be silently changed to 1 (if branch > .5) or 0 (if branch < .5)

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>branch.tweak</td>
<td>Default 1. Applies only if branch.type is nonzero. Use this argument to scale the widths of the branches, for example, branch.tweak=.5 to halve the width of the branches. (By default, prp normalizes the widths so the widest branch is one-fifth the plot width.)</td>
</tr>
<tr>
<td>min.branch.width</td>
<td>Default .002. Applies only if branch.type is nonzero. The minimum width of a branch, as a fraction of the page width. The width of branches that would be thinner than min.branch.width is clamped. Increase min.branch.width if the thinnest branches are too skinny on your display device.</td>
</tr>
<tr>
<td>branch.fill</td>
<td>Color used to fill the wide branch lines. Applies only if branch.type is nonzero. Default branch.col.</td>
</tr>
</tbody>
</table>
The following control the node numbers (with nn=TRUE).

- **nn.cex**: Default NULL, meaning calculate the cex of the node numbers automatically. This and the following arguments apply only when nn=TRUE.
- **nn.font**: Font for the node numbers. Default 3, italic.
- **nn.family**: Font family for the node numbers. Default "".
- **nn.col**: Color of the node number text. Default 1.
- **nn.box.col**: Color of the boxes around the node numbers. Default 0, meaning use the background color.
- **nn.border.col**: Color of the box border around the node numbers. Default nn.col.
- **nn.lty**: Line type of the node number box border. Default 1.
- **nn.lwd**: Line width of the node box border relative to cex (which by default is calculated automatically). Default NULL, meaning use lwd (which can be passed in as a ...argument).
- **nn.round**: Controls the rounding of the corners of the node number boxes. Default .3, meaning small corners. Else specify a value greater than or equal to 0.

**yes.text, no.text**

Text displayed when yesno=TRUE. Default yes.text="yes" and no.text="no".

The following are user definable functions.

- **node.fun**: The function that generates the text at the node labels. The default is NULL, which means use a default function internal to prp. (This is necessary for full support of extra as described in the section on extra above.) Otherwise set node.fun to your own function with the prototype function(x, labs, digits, varlen)
  
- **split.fun**: The function that generates the text at the splits. The default is NULL, which means use a default function internal to prp. Otherwise set split.fun to your own function with the prototype function(x, labs, digits, varlen, faclen)

**FUN**

The function that displays the text on the screen. Default text.

The following are esoteric parameters, mostly for the graph layout engine.

- **nspace**: Applies only when compress=TRUE. Default nspace=branch. The size of the space between a split and a leaf, relative to the space between leaves.
- **minbranch**: Applies only when uniform=FALSE. Default .3. The minimum height between levels is clamped at minbranch times the mean interlevel distance. Needed because sometimes a split gives little or no improvement in deviance, and an interlevel distance strictly proportional to the improvement would leave no room for the label.
- **do.par**: Default TRUE, meaning adjust the mar parameter so the tree fills the figure region. This also sets xpd=NA. These graphic parameters are restored to their original state before prp exits. If you explicitly set mar or xpd, prp will use your setting regardless of the setting of do.par.
- **add.labs**: Default TRUE, meaning display the labels. If FALSE, gives a bare bones display similar to plot.rpart.
clip.left.labs  Like clip.right.labs but for the left labels. Default is FALSE. Note that
clip.left.labs and clip.right.labs can be vectors, indexed on the split
number.

fam.main  Font family for the main text. Default "". The (inconsistent) name was chosen
to minimize partial matching with main and family which can be passed in as
in as . . . arguments.

yshift  Vertical position of the labels, in character heights relative to their default po-
position. Default \(0\). Negative values move the text down; positive up (the box
around the text will follow along).

space  Horizontal space to the box border on each side of the node label text, in char-
acter widths. Default 1. Use this (and yspace) for bigger boxes. Since this
affects the size of the (possibly invisible) boxes, it also affects the graph layout
and hence also the automatic calculation of cex.

yspace  Vertical space to the box border above and below the node label text, in character
heights. Default space. See the comments for space.

shadow.offset  Offset of the shadow from the boxes, in character widths. Default \(.4\) (but the
shadow will be invisible unless the default shadow.col is changed).

split.adj  Horizontal position of the split text. In string width units, as is the conven-
tion for adj arguments. Default NULL, meaning use adj (which defaults to 0.5 but
can be passed in as a . . . argument). Use values less/more than \(.5\) to shift the
text left/right (the box around the text will follow along).

split.yshift  Vertical position of the split labels, in character heights relative to their default
positions. Default \(0\). Negative values move the text down; positive up (the box
around the text will follow along). This adjusts the positions of the split labels
relative to the node labels. (Use yshift if you want to shift both the split and
node labels.)

split.space  Horizontal space between the split label text and the box, in character widths.
Default space. Affects the size of the box drawn around the text. The split
boxes are by default invisible (see split.box.col and split.border.col),
but nevertheless affect the graph layout used in the automatic calculation of cex.

split.yspace  Vertical space between the split label text and the box, in character heights.
Default yspace.

split.shadow.offset  Offset of the shadow from the split boxes, in character widths. Default shadow.offset.
(but the shadow will be invisible unless the default shadow.col is changed).

nn.adj  Horizontal position of the node label text. Default \(.5\).

nn.yshift  Vertical position of the node numbers, in character heights relative to their de-
fault positions. Default \(0\).

nn.space  Horizontal space to the box border on each side of the node number text, in char-
acter widths. Default \(.8\).

nn.yspace  Vertical space to the box border above and below the node number text, in char-
acter heights. Default \(.5\).

under.ygap  Applies if text is plotted under the box (i.e. if under=TRUE or there is a double
newline in prefix or suffix). Vertical gap (in char heights) between the lower
eedge of the box and the top of the text under the box.
yesno.yshift  Vertical position of "yes" and "no" in character heights relative to their default position. Default 0. Applies only when yesno=TRUE.

ygap  Minimum vertical gap between boxes, in character heights. Default gap/2.

xcompact  If TRUE (the default) and there is too much white space, automatically change xlim to compact the entire tree horizontally. This usually only activates for small trees. (The xcompact and ycompact arguments compact the tree as a whole, whereas the compress and ycompress arguments move parts of the tree into available space.)

ycompact  If TRUE (the default) and there is too much vertical space, automatically change ylim to compact the entire tree vertically.

xcompact.ratio  Default .8. Applies only when xcompact=TRUE. The maximum possible without overplotting is 1, but compacting by .8 usually gives more pleasing spacing (it gives more space).

min.inter.height  Default 4. Applies only when ycompact=TRUE. Minimum height (in units of character height) between the lowest label in a layer and the highest label in the layer below it.

max.auto.cex  Clamp the maximum automatically calculated cex at this value Default 1, meaning never expand cex, only contract when necessary.

min.auto.cex  Default .15. Never downscale to less than this when automatically calculating cex, even if overplotted labels result. (The graph layout algorithm is unstable with cex's below 0.15 – meaning that the automatic type size may be smaller than necessary.)

ycompress.cex  Default .7. Applies only when ycompress=TRUE. Apply the ycompress algorithm if the initial automatically calculated cex is less than this. The idea is that we don’t want to shift if we get an acceptable cex without shifting. Make Inf to always attempt shifting.

accept.cex  Accept shifting only if it causes at least this much improvement in cex (because we don’t want to shift if it gives only a small improvement in cex). Default 1.1 i.e. require at least a 10% improvement. Use 0 to always accept shifts and Inf to never accept (or use ycompress=FALSE).

shift.amounts  Default c(1.5, 2, 3). For ycompress, choose the best cex yielded by shifting nodes by these amounts, in multiples of the box heights (after initial scaling).

Fallen.yspace  Extra space for fallen leaves. Default 0, meaning allow 10% of the vertical space for the fallen leaves. (The name Fallen.yspace uses upper case to avoid partial matching with fallen.leaves.)

boxes.include.gap  Default FALSE. Include gap and ygap when drawing the boxes, for debugging purposes. (To draw the boxes, see box.col, border.col, split.box.col, and split.border.col.) This argument only affects the way the boxes are drawn, not the graph layout algorithm in any way. With the optimum cex at least one pair of boxes displayed in this manner will just touch (but none will overlap).

legend.x  Applies only to models with a multilevel class response (not binary or anova models, for which no legend is drawn). Horizontal position of the legend. Typically a value between 0 and 1, although values beyond those limits are often
useful. Default is NULL meaning automatically position the legend (assuming there is enough space). Use NA for no legend.

**legend.y**
Like `legend.x` but for the vertical position of the legend.

**legend.cex**
Like `legend.x` but for the relative size of the legend text. Default is 1.

... Extra `par` arguments. Only the “important” `par` arguments are supported. Note that arguments like `col` apply only to the node labels. To affect the split labels or branch lines, use `split.col` and `branch.col` instead.

**Value**
A list with the following components. With the default args most of these are calculated automatically.

- **obj** The `rpart` object. Identical to the `x` argument passed in unless `snip` was used.
- **snipped.nodes** The snipped nodes, NULL unless `snip` was used.
- **xlim, ylim** The graph limits.
- **x, y** The node coords.
- **branch.x, branch.y** The branch line coords.
- **labs** The node labels.
- **cex** The node label `cex`.
- **boxes** The coords of the boxes around the nodes.
- **split.labs** The split labels.
- **split.cex** The split label `cex`.
- **split.boxes** The coords of the boxes around the splits.

**Examples**

```r
data(ptitanic)
tree <- rpart(survived ~ ., data=ptitanic, cp=.02)
  # cp=.02 because want small tree for demo

old.par <- par(mfrow=c(2,2))
  # put 4 figures on one page

prp(tree, main="default prp\n(type = 0, extra = 0)")

prp(tree, main="type = 4, extra = 6\nbox.palette = \"auto\",
```
type=4, extra=6,  # label all nodes, show prob of second class
box.palette="auto",  # auto color the nodes based on the model type
faclen=0)  # faclen=0 to print full factor names

cols <- ifelse(tree$frame$yval == 1, "darkred", "green4")
  # green if survived

prp(tree, main="assorted arguments",
  extra=1:6,  # display prob of survival and percent of obs
  nn=TRUE,  # display the node numbers
  fallen.leaves=TRUE,  # put the leaves on the bottom of the page
  shadow.col="gray",  # shadows under the leaves
  branch.lty=3,  # draw branches using dotted lines
  branch=5,  # change angle of branch lines
  faclen=0,  # faclen=0 to print full factor names
  trace=1,  # print the automatically calculated cex
  split.cex=1.2,  # make the split text larger than the node text
  split.prefix="is ",  # put "is " before split text
  split.suffix="?",  # put "?" after split text
  col=cols, border.col=cols,  # green if survived
  split.box.col="lightgray",  # lightgray split boxes (default is white)
  split.border.col="darkgray",  # darkgray border on split boxes
  split.round=5)  # round the split box corners a tad

# compare to the plotting functions in the rpart package
plot(tree, uniform=TRUE, compress=TRUE, branch=.2)

par(old.par)

---

**ptitanic**

Titanic data with passenger names and other details removed.

**Description**

Titanic data with passenger names and other details removed.

**Format**

A data frame with 1046 observations on 6 variables.

- **pclass**: passenger class, unordered factor: 1st 2nd 3rd
- **survived**: factor: died or survived
- **sex**: unordered factor: male female
- **age**: age in years, min 0.167 max 80.0
- **sibsp**: number of siblings or spouses aboard, integer: 0...8
- **parch**: number of parents or children aboard, integer: 0...6
The dataset was compiled by Frank Harrell and Robert Dawson:

See also:
http://biostat.mc.vanderbilt.edu/twiki/pub/Main/DataSets/titanic3info.txt.

For this version of the Titanic data, passenger details were deleted, survived was cast as a factor, and the name changed to ptitanic to minimize confusion with other versions.

In this data the crew are conspicuous by their absence.

Contents of ptitanic:

<table>
<thead>
<tr>
<th>pc</th>
<th>cl</th>
<th>s</th>
<th>s</th>
<th>p</th>
<th>a</th>
<th>p</th>
<th>a</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
<td>2</td>
<td>2</td>
<td>2</td>
<td>2</td>
<td>2</td>
<td>2</td>

</tr>
<tr>
<td>5</td>
<td>5</td>
<td>5</td>
<td>5</td>
<td>5</td>
<td>5</td>
<td>5</td>
<td>5</td>
</tr>
</tbody>
</table>

How ptitanic was built:

```r
load("titanic3.sav")  # from Dr. Harrell's web site
# discard name, ticket, fare, cabin, embarked, body, home.dest
ptitanic <- titanic3[,c(1,2,4,5,6,7)]
# change survived from integer to factor
ptitanic$survived <- factor(ptitanic$survived, labels=c("died", "survived"))
save(ptitanic, file="ptitanic.rda")
```

This version of the data differs from etitanic in the earth package in that here survived is a factor (not an integer) and age has some NAs.

Examples

```r
data(ptitanic)
summary(ptitanic)
# main indicator of missing data is 3rd class esp. with many children
obs.with.nas <- rowSums(is.na(ptitanic)) > 0
prp(rpart(obs.with.nas~., data=ptitanic, method="class"),
  main="observations with missing data", extra=7)
```
rpart.plot

Plot an rpart model. A simplified interface to the prp function.

Description

Plot an rpart model, automatically tailoring the plot for the model’s response type.

For an overview, please see the package vignette Plotting rpart trees with the rpart.plot package.

This function is a simplified front-end to prp, with only the most useful arguments of that function, and with different defaults for some of the arguments.

The different defaults for the extra and col.palette arguments mean that this function automatically creates a colored plot suitable for the type of model (whereas prp by default creates a minimal plot). In detail the different defaults are:

<table>
<thead>
<tr>
<th>rpart.plot</th>
<th>prp</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>2</td>
</tr>
<tr>
<td>extra</td>
<td>“auto”</td>
</tr>
<tr>
<td>fallen.leaves</td>
<td>TRUE</td>
</tr>
<tr>
<td>varlen</td>
<td>0</td>
</tr>
<tr>
<td>faclen</td>
<td>0</td>
</tr>
<tr>
<td>box.palette</td>
<td>“auto”</td>
</tr>
</tbody>
</table>

The function rpart.plot.version1 is compatible with old versions of this function and has the same defaults as prp.

Usage

rpart.plot(x=stop("no 'x' arg"),
           type=2, extra="auto",
           under=FALSE, fallen.leaves=TRUE,
           digits=2, varlen=0, faclen=0,
           cex=NULL, tweak=1,
           snip=FALSE,
           box.palette="auto", shadow.col=0,
           ...
)

Arguments

To start off, look at the arguments x, type and extra. Just those arguments will suffice for many users. If you don’t want a colored plot, use box.palette=0.

An rpart object. The only required argument.

**type**

Type of plot. Possible values:

0 Draw a split label at each split and a node label at each leaf.
1 Label all nodes, not just leaves. Similar to text.rpart's all=TRUE.
2 Default. Like 1 but draw the split labels below the node labels. Similar to the plots in the CART book.
3 Draw separate split labels for the left and right directions.
4 Like 3 but label all nodes, not just leaves. Similar to text.rpart’s fancy=TRUE. See also clip.right.labs.

**extra**
Display extra information at the nodes. Possible values:
"auto" (case insensitive) Default. Automatically select a value based on the model type, as follows:
extra=106 class model with a binary response
extra=104 class model with a response having more than two levels
extra=100 other models

0 No extra information.
1 Display the number of observations that fall in the node (per class for class objects; prefixed by the number of events for poisson and exp models). Similar to text.rpart’s use.n=TRUE.
2 Class models: display the classification rate at the node, expressed as the number of correct classifications and the number of observations in the node. Poisson and exp models: display the number of events.
3 Class models: misclassification rate at the node, expressed as the number of incorrect classifications and the number of observations in the node.
4 Class models: probability per class of observations in the node (conditioned on the node, sum across a node is 1).
5 Class models: like 4 but do not display the fitted class.
6 Class models: the probability of the second class only. Useful for binary responses.
7 Class models: like 6 but do not display the fitted class.
8 Class models: the probability of the fitted class.
9 Class models: the probabilities times the fraction of observations in the node (the probability relative to all observations, sum across all leaves is 1).
+100 Add 100 to any of the above to also display the percentage of observations in the node. For example extra=101 displays the number and percentage of observations in the node. Actually, it’s a weighted percentage using the weights passed to rpart.

Note 1: Unlike text.rpart, by default prp uses its own routine for generating node labels (not the function attached to the object). See the node.fun argument of prp.
Note 2: The extra argument has special meaning for mpart objects. See the Appendix to this package’s vignette.

**under**
Applies only if extra > 0. Default FALSE, meaning put the extra text in the box. Use TRUE to put the text under the box.

**fallen.leaves**
Default TRUE to position the leaf nodes at the bottom of the graph. It can be helpful to use FALSE if the graph is too crowded and the text size is too small.
digits

The number of significant digits in displayed numbers. Default 2.
If 0, use `getOption("digits")`. If negative, use the standard `format` function (with the absolute value of digits).

When `digits` is positive, the following details apply:
Numbers from 0.001 to 9999 are printed without an exponent (and the number of digits is actually only a suggestion, see `format` for details). Numbers out that range are printed with an “engineering” exponent (a multiple of 3).

varlen

Length of variable names in text at the splits (and, for class responses, the class in the node label). Default 0, meaning display the full variable names. Possible values:

0 use full names (default).

greater than 0 call `abbreviate` with the given `varlen`.

less than 0 truncate variable names to the shortest length where they are still unique, but never truncate to shorter than `abs(varlen)`.

faclen

Length of factor level names in splits. Default 0, meaning display the full factor names. Possible values are as `varlen` above, except that for back-compatibility with `text.rpart` the special value 1 means represent the factor levels with alphabetic characters (a for the first level, b for the second, etc.).

cex

Default `NULL`, meaning calculate the text size automatically.

tweak

Adjust the (possibly automatically calculated) `cex`. Default 1, meaning no adjustment. Use say `tweak=1.2` to make the text 20% larger. However, since font sizes are discrete the `cex` you ask for may not be exactly the `cex` you get. And a small change to `tweak` may not actually change the type size, or change it more than you want.

snip

Default `FALSE`. Set `TRUE` to interactively trim the tree with the mouse. See the package vignette (or just try it).

box.palette

Palette for coloring the node boxes based on the fitted value. This is a vector of colors, for example `box.palette=c("green", "green2", "green4")`. Small fitted values are displayed with colors at the start of the vector; large values with colors at the end.

The special value `box.palette=0` (default for `prp`) uses the background color (typically white).

The special value `box.palette="auto"` (default for `rpart.plot`, case insensitive) automatically selects a predefined palette based on the type of model.

Otherwise specify a predefined palette e.g. `box.palette="Grays"` for the predefined gray palette (a range of grays). The predefined palettes are (see the `show.prp.palettes` function):

Grays Greys Greens Blues Browns Oranges Reds Purples
Gy Gn Bu Bn Or Rd Pu (alternative names for the above palettes)
BuGn GnRd BuDr etc. (two-color diverging palettes: any combination of two of
the above palettes)
RdYlGn GrnY1Rd BlGnY1 Y1GnBl (three color palettes)
Prefix the palette name with "-" to reverse the order of the colors
e.g. box.palette="-auto" or box.palette="-Grays".
shadow.col  Color of the shadow under the boxes. Default 0, no shadow. Try "gray" or "darkgray".
...  Extra arguments passed to prp and the plotting routines. Any of prp’s arguments
can be used.

Value
The returned value is identical to that of prp.

Author(s)
Stephen Milborrow, borrowing heavily from the rpart package by Terry M. Therneau and Beth Atkinson, and the R port of that package by Brian Ripley.

The package vignette Plotting rpart trees with the rpart.plot package

prp

rpart.plot.version1

Functions in the rpart package: plot.rpart text.rpart rpart

Examples
old.par <- par(mfrow=c(2,2))  # put 4 figures on one page
data(ptitanic)

#-----------------------------------------------

binary.model <- rpart(survived ~ ., data=ptitanic, cp=.02)
  # cp=.02 for small demo tree
rpart.plot(binary.model,
     main="titanic survived\n(binary response)")
rpart.plot(binary.model,
     box.palette="Grays",  # override default GnBu palette
     main="titanic survived\nbox.palette = \"Grays\"")

#-----------------------------------------------
anova.model <- rpart(Mileage ~ ., data=cu.summary)
rpart.plot.version1

Plot an rpart model (old version).

Description
This function is provided for backward compatibility with old versions of rpart.plot (prior to version 2.0.0, June 2016).
By default this function creates a minimal unadorned plot, whereas rpart.plot creates a colored plot automatically tailored to the model's type.
Actually, the only difference between the two functions is that some arguments have different defaults. This function has the same defaults as prp. See the rpart.plot help page for a table showing the different defaults.

Usage
rpart.plot.version1(x=stop("no 'x' arg"),
type=0, extra=0,
under=FALSE, fallen.leaves=FALSE,
digits=2, varlen=-8, faclen=3,
cex=NULL, tweak=1,
snip=FALSE,
box.palette=0, shadow.col=0,
...)

Arguments
x Same as rpart.plot.
type
extra
under
fallen.leaves
digits
varlen

Same as rpart.plot.
Default 0. Same as rpart.plot.
Default 0, otherwise the same as rpart.plot (which has a default of "auto").
Default FALSE. Same as rpart.plot.
Default FALSE, otherwise the same as rpart.plot (which has a default of TRUE).
Default 2. Same as rpart.plot.
Default ~8, otherwise the same as rpart.plot (which has a default of 0).
show.prp.palettes

faclen  Default 3, otherwise the same as \texttt{rpart.plot} (which has a default of \(0\)).
cex  Default \texttt{NULL}. Same as \texttt{rpart.plot}.
tweak  Default 1. Same as \texttt{rpart.plot}.
snip  Default FALSE. Same as \texttt{rpart.plot}.
box.palette  Default \(0\), otherwise the same as \texttt{rpart.plot} (which has a default of "auto").
shadow.col  Default \(0\). Same as \texttt{rpart.plot}.
...

Value

The returned value is identical to that of \texttt{prp}.

Examples

data(\texttt{ptitanic})

\begin{verbatim}
tree <- \texttt{rpart}(survived ~ ., data=\texttt{ptitanic}, cp=\texttt{.02})
  # \texttt{cp}=\texttt{.02} because want small tree for demo

old.par <- \texttt{par mfrow=c(2,2))}
  # put 4 figures on one page

\texttt{rpart.plot.version1(tree, main="default rpart.plot.version1\\n(type = 0, extra = 0)")}

\texttt{rpart.plot.version1(tree, main="type = 4, extra = 6",}
  \texttt{type=4, extra=6, faclen=0})  # faclen=0 to print full factor names

\texttt{rpart.plot.version1(tree, main="extra = 106, under = TRUE",}
  \texttt{extra=106, under=TRUE, faclen=0})
\end{verbatim}

\begin{verbatim}
# compare to the plotting functions in the \texttt{rpart} package
\texttt{plot(tree, uniform=TRUE, compress=TRUE, branch=.2)}
\texttt{text(tree, use.n=TRUE, cex=.8, xpd=NA)}  # cex is a guess, depends on your window size
\texttt{title("compare to the plotting functions\nin the \texttt{rpart} package", cex.sub=.8)}
par(old.par)
\end{verbatim}

\begin{verbatim}
show.prp.palettes  \textit{Show the built-in prp palettes.}
\end{verbatim}

Description

Display a diagram showing the built-in palettes accepted by \texttt{prp}'s \texttt{box.palette} argument.

Usage

\texttt{show.prp.palettes()}
Examples

show.prp.palettes()
