Package ‘directlabels’

September 1, 2023

Maintainer  Toby Dylan Hocking <toby.hocking@r-project.org>
Author  Toby Dylan Hocking
Version  2023.8.25

BugReports  https://github.com/tdhock/directlabels/issues
License  GPL-3
Title  Direct Labels for Multicolor Plots
Description  An extensible framework for automatically placing direct labels onto multicolor 'lattice' or 'ggplot2' plots. Label positions are described using Positioning Methods which can be re-used across several different plots. There are heuristics for examining `trellis" and `ggplot" objects and inferring an appropriate Positioning Method.

ahull.grid  ahull grid

Description
Label the closest point on the alpha hull of the data.

Usage
"ahull.grid"

ahull.points  ahull points

Description
Calculate the points on the ashape.

Usage
ahull.points(d, ..., 
    ahull = default.ahull(d))
angled.boxes

Arguments

d  d
...
ahull  ahull

Author(s)

Toby Dylan Hocking

Description

Draw a box with the label inside, at the point furthest away from the plot border and any other curve.

Usage

"angled.boxes"

angled.endpoints  angled endpoints

Description

Useful for labeling lines that all end at the top.

Usage

"angled.endpoints"
apply.method

Apply a Positioning Method

Description

Run a Positioning Method list on a given data set. This function contains all the logic for parsing a Positioning Method and sequentially applying its elements to the input data to obtain the label positions.

Usage

apply.method(method, d, columns.to.check = c("x", "y", "groups", "label"), ..., debug = FALSE)

Arguments

method  Direct labeling Positioning Method. Starting from the data frame of points to plot for the panel, the elements of the Positioning Method list are applied in sequence, and then each row of the resulting data frame is used to draw a direct label. The elements of a Positioning Method list can be

• a Positioning Function is any function(d, ...) which takes a data.frame d with columns x,y,groups and returns another data.frame representing the positions of the desired direct labels. For a description of all the columns that are interpreted for drawing direct labels, see drawDetails.dlgrab. For example, maxvar.points is a Positioning Function that returns a data.frame with columns x,y,groups,hjust,vjust.

• a character vector of length 1 is treated as the name of an R object. For example, specifying "maxvar.points" means to look up the variable called maxvar.points and use that. Using the name of a Positioning Function is preferable to specifying the Positioning Function itself, since then the name is visible in the Positioning Method list, which is more interpretable when debugging.

• a named list element is used to add or update variables in the data.frame of direct labels to plot. For example list("first.points",cex=1.5) means take only the first points of every group and then set the cex column to 1.5.

• an element of a Positioning Method list can be another Positioning Method list, in which case the elements of the inner list are applied.

d  Data frame to which we apply the Positioning Method. The x and y columns should be in centimeters (cm), so that Positioning Methods can easily calculate the L2/Euclidean/visual distance between pairs of points.

columns.to.check  After applying each Positioning Method list element, we check for the presence of these columns, and if not found we stop with an error.
... Named arguments, passed to Positioning Functions.

deploy debug If TRUE, print each Positioning Method list element and the direct label data.frame that results from its evaluation.

Value
The final data frame returned after applying all of the items in the Positioning Method list, with x and y in units of cm.

Author(s)
Toby Dylan Hocking

---

<table>
<thead>
<tr>
<th>big.boxes</th>
<th>big boxes</th>
</tr>
</thead>
</table>

Description
Calculate big boxes around the means of each cluster.

Usage
"big.boxes"

---

<table>
<thead>
<tr>
<th>bottom.pieces</th>
<th>bottom pieces</th>
</tr>
</thead>
</table>

Description
Positioning Method for the bottom of a group of points.

Usage
bottom.pieces(d, ...)

Arguments
d
d...

Author(s)
Toby Dylan Hocking
bottom.points  

**Description**  
Positioning Method for the bottom of a group of points.

**Usage**  
```
bottom.points(d, ...)  
```

**Arguments**
- `d`  

**Author(s)**
Toby Dylan Hocking

---

bottom.polygons  

**Description**  
Draw a speech polygon to the bottom point.

**Usage**
```
"bottom.polygons"  
```

---

bumpup  

**Description**  
Sequentially bump labels up, starting from the bottom, if they collide with the label underneath.

**Usage**
```
bumpup(d, ...)  
```
**calc.borders**

**Arguments**

- `d` Data frame of point labels, with new widths and heights in the w and h columns.
- `...` ignored.

**Author(s)**

Toby Dylan Hocking

**Description**

Calculate bounding box based on newly calculated width and height.

**Usage**

```r
calc.borders(d, ..., debug = FALSE)
```

**Arguments**

- `d` Data frame of point labels, with new widths and heights in the w and h columns.
- `...` ignored.

**Author(s)**

Toby Dylan Hocking

**calc.boxes**

**Description**

Calculate boxes around labels, for collision detection.

**Usage**

```r
calc.boxes(d, debug = FALSE, ...)
```

**Arguments**

- `d` Data frame of point labels, with new widths and heights in the w and h columns.
- `debug` debug
- `...` ignored.
check.for.columns

Description
Stop if a data.frame does not have some columns.

Usage
check.for.columns(d, must.have)

Arguments

Author(s)
Toby Dylan Hocking

chull.grid

Description
Label the closest point on the convex hull of the data.

Usage
“chull.grid”
chull.points

Description
Calculate the points on the convex hull.

Usage
chull.points(d, ...)

Arguments
d d
... ...

Author(s)
Toby Dylan Hocking

default.ahull

default ahull

Description
Calculate the default alpha parameter for ashape based on the average size of label boxes.

Usage
default.ahull(d, ...)

Arguments
d d
... ...

Author(s)
Toby Dylan Hocking
default_picker

Description
Look at options() for a user-defined default Positioning Method picker, and use that (or the hard-coded default picker), with the calling environment to figure out a good default.

Usage
default_picker(f)

Arguments
f
Object class to look for (trellis or ggplot).

Author(s)
Toby Dylan Hocking

defaultpf.ggplot

Description
Default method selection method for ggplot2 plots.

Usage
defaultpf.ggplot(geom, p, L, colvar, ...)

Arguments
geom
p
L
colvar
...

Author(s)
Toby Dylan Hocking
defaultpf.trellis

Description
If no Positioning Method specified, choose a default using this function. The idea is that this is called with all the variables in the environment of panel.superpose.dl, and this can be user-customizable by setting the directlabels.defaultpf.lattice option to a function like this.

Usage

defaultpf.trellis(lattice.fun.name, groups, type, ...)

Arguments

lattice.fun.name
  lattice.fun.name

  groups
groups

type
type

...
...

Author(s)

Toby Dylan Hocking

direct.label

Direct labels for color decoding

Description
Add direct labels to a plot, and hide the color legend. Modern plotting packages like lattice and ggplot2 show automatic legends based on the variable specified for color, but these legends can be confusing if there are too many colors. Direct labels are a useful and clear alternative to a confusing legend in many common plots.

Usage

direct.label(p, method = NULL, debug = FALSE)
Arguments

\( p \)  
The "trellis" or "ggplot" object with things drawn in different colors.

\( \text{method} \)  
Positioning Method, which determines the positions of the direct labels as a function of the plotted data. If NULL, we examine the plot \( p \) and try to choose an appropriate default. See \texttt{apply.method} for more information about Positioning Methods.

\( \text{debug} \)  
Show debug output?

Value

A plot with direct labels and no color legend.

Author(s)

Toby Dylan Hocking

Examples

```r
if(require(ggplot2)){
  ## Add direct labels to a ggplot2 scatterplot, making sure that each
  ## label is close to its point cloud, and doesn't overlap points or
  ## other labels.
  scatter <- qplot(jitter(hwy),jitter(cty),data=mpg,colour=class,
                   main="Fuel efficiency depends on car size")
  direct.label(scatter)
}

## direct labels for lineplots that do not overlap and do not go off
## the plot.
if(require(nlme) && require(lattice)){
  oldopt <- lattice.options(panel.error=NULL)
  ratplot <- xyplot(weight~Time|Diet,BodyWeight,groups=Rat,type='l',layout=c(3,1))
  ## Using the default Positioning Method (maxvar.qp), the labels are
  ## placed on the side which is most spread out, so in multipanel
  ## plots they sometimes end up on different sides.
  print(direct.label(ratplot))
  ## To put them on the same side, just manually specify the
  ## Positioning Method.
  print(direct.label(ratplot,"last.qp"))
  lattice.options(oldopt)
}
```
Description

Direct label a ggplot2 grouped plot.

Usage

## S3 method for class 'ggplot'
direct.label(p,
    method = NULL, debug = FALSE)

Arguments

  p          The ggplot object.
  method     Method for direct labeling as described in apply.method.
  debug      Show debug output?

Value

The ggplot object with direct labels added.

Author(s)

  Toby Dylan Hocking

Description

Add direct labels to a grouped lattice plot. This works by parsing the trellis object returned by the
high level plot function, and returning it with a new panel function that will plot direct labels using
the specified method.

Usage

## S3 method for class 'trellis'
direct.label(p,
    method = NULL, debug = FALSE)
dl.combine

**Arguments**

- `p` The lattice plot (result of a call to a high-level lattice function).
- `method` Method for direct labeling as described in `apply.method`.
- `debug` Show debug output?

**Value**

The lattice plot.

**Author(s)**

Toby Dylan Hocking

---

**dl.combine**

*Combine output of several methods*

**Description**

Apply several Positioning methods to the original data frame.

**Usage**

`dl.combine(...)`

**Arguments**

... Several Positioning Methods.

**Value**

A Positioning Method that returns the combined data frame after applying each specified Positioning Method.

**Author(s)**

Toby Dylan Hocking

**Examples**

```r
## Simple example: label the start and endpoints
if(require(nlme) && require(lattice)){
  ratplot <- xyplot(
    weight~Time|Diet,BodyWeight,groups=Rat,type='l',layout=c(3,1))
  both <- dl.combine("first.points","last.points")
  rat.both <- direct.label(ratplot,"both")
  print(rat.both)
  ## same as repeated call to direct.label:
```
rat.repeated <-
   direct.label(direct.label(ratplot,"last.points"),"first.points")
print(rat.repeated)
}

## same with ggplot2:
if(require(nlme) && require(ggplot2)){
  rp2 <- qplot(
    Time,weight,data=BodyWeight,geom="line",facets=~Diet,colour=Rat)
  print(direct.label(direct.label(rp2,"last.points"),"first.points"))
  print(direct.label(rp2,"both"))
}

## more complex example: first here is a function for computing the
## lasso path.
mylars <- function
## Least angle regression algorithm for calculating lasso solutions.
(x,
## Matrix of predictor variables.
y,
## Vector of responses.
epsilon=1e-6
## If correlation < epsilon, we are done.
)(
  xscale <- scale(x) # need to work with standardized variables
  b <- rep(0,ncol(x))# coef vector starts at 0
  names(b) <- colnames(x)
  ycor <- apply(xscale,2,function(xj)sum(xj*y))
  j <- which.max(ycor) # variables in active set, starts with most correlated
  alpha.total <- 0
  out <- data.frame()
  while(1){## lar loop
    xak <- xscale[,j] # current variables
    r <- y-xscale%*%b # current residual
    delta <- solve(t(xak)%*%xak)%*%t(xak)%*%r
    intercept <- apply(xscale,2,function(xk)sum(r*xk))
    slope <- apply(xscale,2,function(xk)-sum(z*xk))
    out <- rbind(out,data.frame(variable=colnames(x),
      coef=b,
      corr=abs(intercept),
      alpha=alpha.total,
      arclength=sum(abs(b)),
      coef.unscaled=b/attr(xscale,"scaled:scale")))
    if(sum(abs(intercept)) < epsilon)#corr==0 so we are done
      return(transform(out,s=arclength/max(arclength)))
    ## If there are more variables we can enter into the regression,
    ## then see which one will cross the highest correlation line
    ## first, and record the alpha value of where the lines cross.
d <- data.frame(slope, intercept)
d[d$intercept<0,] <- d[d$intercept<0,]*-1

do <- data.frame(d[j[j]],)# highest correlation line
d2 <- data.frame(rbind(d,-d),variable=names(slope))#reflected lines
## Calculation of alpha for where lines cross for each variable
d2$alpha <- (d0$intercept-d2$intercept)/(d2$slope-d0$slope)
subd <- d2[(!d2$variable%in%colnames(x)[j])&d2$alpha>epsilon,]
subd <- subd[which.min(subd$alpha),]
nextvar <- subd$variable
alpha <- if(nrow(subd))subd$alpha else 1
## If one of the coefficients would hit 0 at a smaller alpha
## value, take it out of the regression and continue.
hit0 <- xor((b[j]>0, delta>0)&b[j]!=0
alpha0 <- -b[j][hit0]/delta[hit0]
takeout <- length(alpha0)&&min(alpha0) < alpha
if(takeout){
  i <- which.min(alpha0)
  alpha <- alpha0[i]
}
b[j] <- b[j]+alpha*delta ## evolve parameters
alpha.total <- alpha.total+alpha
## add or remove a variable from the active set
j <- if(takeout)[j]=which(names(i)==colnames(x)]
  else c(j,which(nextvar==colnames(x)))
}

## Calculate lasso path, plot labels at two points: (1) where the
## variable enters the path, and (2) at the end of the path.
if(require(lars) && require(lattice)){
  data(diabetes, envir=environment())
dres <- with(diabetes, mylars(x,y))
P <- xyplot(coef~arclength, dres, groups=variable, type="l")
mylasso <- dl.combine("lasso.labels", "last.qp")
plot(direct.label(P,"mylasso")
}

---

**dl.env**

**dl env**

**Description**

This environment holds an integer id that will be incremented to get a unique id for each dlgrob.

**Usage**

"dl.env"
Description
Jitter the label positions.

Usage
dl.jitter(d, ...)

Arguments
d d
... ...

Author(s)
Toby Dylan Hocking

Description
Manually move a direct label

Sometimes there is 1 label that is placed oddly by another Positioning Function. This function can be used to manually place that label in a good spot.

Usage
dl.move(group, x, y,
...)

Arguments
group Group to change.
x Horizontal position of the new label.
y Vertical position of the new label. If missing(y) and !missing(x) then we will calculate a new y value using linear interpolation.
... Variables to change for the specified group

Value
A Positioning Function that moves a label into a good spot.
dl.summarize

**Author(s)**

Toby Dylan Hocking

**Examples**

```r
if(require(ggplot2) && require(lattice)){
  scatter <- xyplot(jitter(cty)~jitter(hwy),mpg,groups=class,aspect=1)
  dlcompare(list(scatter),
            list("extreme.grid",
                 "+dl.move"="list(extreme.grid,dl.move("suv",15,15)))
  p <- qplot(log10(gamma),rate,data=svmtrain,group=data,colour=data,
             geom="line",facets=replicate~nu)
  adjust.kif <- dl.move("KIF11",-0.9,hjust=1,vjust=1)
  dlcompare(list(p+xlim(-8,7)),
            list("last.points",
                 "+dl.move"="list(last.points,adjust.kif))
}
```

---

dl.summarize

**Description**

summarize which preserves important columns for direct labels.

**Usage**

dl.summarize(OLD, ...)

**Arguments**

OLD    data frame

...    ...

**Author(s)**

Toby Dylan Hocking
**dl.trans**

Direct label data transform

**Description**

Make a function that transforms the data. This is for conveniently making a function that calls transform on the data frame, with the arguments provided. See examples.

**Usage**

dl.trans(...)

**Arguments**

...  
Arguments to pass to transform.

**Value**

A Positioning Function.

**Author(s)**

Toby Dylan Hocking

**Examples**

```r
complicated <- list(dl.trans(x=x+10),
    gapply.fun(d[-2,]),
    rot=c(30,180))
if(require(lattice)){
    direct.label(dotplot(VADeaths,type="o"),complicated,TRUE)
}
```

---

**dlcompare**

Direct label comparison plot

**Description**

Compare several plots and/or label placement methods. This creates a custom grid graphics display based on lattice and/or ggplot2 output. Plots will be on the columns and positioning methods will be on the rows.

**Usage**

dlcompare(plots, pos.funs, 
    rects = TRUE, row.items = "plots",
    debug = FALSE)
Arguments

plots List of ggplot2 or lattice plots. List names will be used to annotate the plot.
pos.funs List of label placement methods to apply to each plot. List names, or function names if specified as character strings, will be used to annotate the plot.
rects Draw rectangles around each plot, creating a grid?
row.items If "plots" then put plots on the rows and method on the columns. Otherwise, do the opposite.
debug Show debug output?

Author(s)

Toby Dylan Hocking

Examples

```r
## Compare two plots of the same data using lattice and ggplot2.
deaths.by.sex <- list(male=mdeaths, female=fdeaths)
deaths.list <- list()
for(sex in names(deaths.by.sex)){
  deaths.ts <- deaths.by.sex[[sex]]
  deaths.list[[sex]] <-
    data.frame(year=as.numeric(time(deaths.ts)),
               sex,
               deaths=as.integer(deaths.ts))
}
deaths <- do.call(rbind, deaths.list)
death.plot.list <- list()
if(require(lattice)){
  oldopt <- lattice.options(panel.error=NULL)
death.plot.list["lattice"] <- xyplot(
    deaths~year,deaths,groups=sex,type="l")
}
if(require(ggplot2)){
  death.plot.list["ggplot2"] <- qplot(
    year,deaths,data=deaths,colour=sex,geom="line")
}
if(length(death.plot.list) && names(dev.cur())!="postscript")(##to avoid error on pkg check.
  ## Use some exotic labeling options with different rotation, font
  ## face, family, and alpha transparency.
  exotic <- list("last.points",
                 rot=c(0,180),
                 fontsize=c(10,20),
                 fontface=c("bold","italic"),
                 fontfamily=c("mono","serif"),
                 alpha=c(0.25,1))
  dlcompare(death.plot.list, list(exotic))
}
if(require(lattice))lattice.options(oldopt)
## Compare a legend with direct labels on the same plot.
if(require(ggplot2) && require(nlme)){
```
ggrat <- qplot(Time, weight, data = BodyWeight, 
              colour = Rat, geom = "line", facets = ~ Diet) 
pfuns <- list("legend","direct labels"="last.qp") 
dlcompare(list(ggrat), pfuns, rects = FALSE, row.items = "posfuns")
}

---

dldoc

Make directlabels documentation

Description

Positioning Methods for direct labels are supposed to work with only certain plot types. Each Positioning Method is defined in R/file.R and plot examples are found in tests/doc/file/*.R so that we can automatically assemble a database of example plots from the code.

Usage

dldoc(pkgdir = "..")

Arguments

pkgdir Package directory root.

Value

Matrix of lists describing example plots and matching builtin Positioning Methods.

Author(s)

Toby Dylan Hocking

---

dlgrob
dlgrob

dlgrob

Description

Make a grid grob that will draw direct labels.

Usage

dlgrob(data, method, 
        debug = FALSE, axes2native = identity, 
        ...)
Arguments

data Data frame including points to plot in native coordinates.
method Positioning Method.
debug debug
axes2native axes2native
...
...

Author(s)

Toby Dylan Hocking

draw.polygons  
draw polygons

Description

Draw polygons around label positions.

Usage

draw.polygons(d, ...)

Arguments

d d
don’t do

Author(s)

Toby Dylan Hocking

draw.rects  
draw rects

Description

Positioning Function that draws boxes around label positions. Need to have previously called calc.boxes. Does not edit the data frame.

Usage

draw.rects(d, ...)

**Arguments**

\[ \text{drawDetails.dlgrob} \]

\[ x \quad \text{The } \text{dlgrob} \text{ list object. x$method should be a Positioning Method list and x$data should be a data.frame with the following variables:} \]

\[ \text{x,y} \quad \text{numeric horizontal and vertical positions of direct labels, in native units. These are converted to cm units before applying the Positioning Method.} \]

\[ \text{groups} \quad \text{factor that indices the different groups, and colour indicates the corresponding group colour.} \]

\[ \text{hjust and vjust} \quad (\text{optional}) \text{ numeric values usually in [0,1] that control the justification of the text label relative to the x,y position.} \]

\[ \text{rot} \quad (\text{optional}) \text{ numeric value in [0,360] that specifies the degrees which the text should be rotated.} \]

\[ \text{cex, alpha, fontface, fontfamily} \quad (\text{optional}) \text{ passed to \text{gpar}.} \]

Additionally, x$debug should be set to TRUE or FALSE, and x$axestonative should be a function that converts units shown on the axes to native units of x$data[,c("x","y")].

\[ \text{recording} \quad \text{recording} \]

**Author(s)**

Toby Dylan Hocking
edges.to.outside  

Description

Given a list of edges from the convex or alpha hull, and a list of cluster centers, calculate a point near to each cluster on the outside of the hull.

Usage

edges.to.outside(edges, centers, debug = FALSE,
                 ...)  

Arguments

edges  
centers  
debug  
...  

Author(s)

Toby Dylan Hocking  

empty.grid  

Description

Label placement method for scatterplots that ensures labels are placed in different places. A grid is drawn over the whole plot. Each cluster is considered in sequence and assigned to the point on this grid which is closest to the point given by the input data points. Makes use of attr(d,"orig.data").

Usage

empty.grid(d, debug = FALSE,
           ...)  

Arguments

d  
debug  
...  

Data frame of target points on the scatterplot for each label.

Show debugging info on the plot?

ignored.
Value

Data frame with columns groups x y, 1 line for each group, giving the positions on the grid closest to each cluster.

Author(s)

Toby Dylan Hocking

enlarge.box  

enlarge box

Description

Make text bounding box larger by some amount.

Usage

enlarge.box(d, ...)

Arguments

d  
d

Author(s)

Toby Dylan Hocking

extract.plot  

Extract plot and definition for documentation

Description

Given an R code file, execute it, store the definition, and save the resulting plot in a variable.

Usage

extract.plot(f)

Arguments

f  
R code file with plot example.

Author(s)

Toby Dylan Hocking
extract.posfun

**Extract Positioning Method for documentation**

**Description**

Use inlinedocs to extract comments and definitions from code, then for each item found add the value and its name to the list.

**Usage**

```
extract.posfun(f)
```

**Arguments**

- `f` R code file, which should contain only Positioning Methods that can be used with examples defined in the doc/ subdirectory with the same name.

**Value**

List of lists, each of which describes one Positioning Method defined in `f`.

**Author(s)**

Toby Dylan Hocking

---

extreme.grid

**extreme grid**

**Description**

Label each point cloud near the extremities of the plot region.

**Usage**

```
"extreme.grid"
```
extreme.points

Description
Label the points furthest from the middle for each group.

Usage
extreme.points(d, ...)

Arguments
d
d...

Author(s)
Toby Dylan Hocking

far.from.others.borders

Description
Find the point on each curve which maximizes the distance to the plot border or to another curve.

Usage
far.from.others.borders(all.groups,
..., debug = FALSE)

Arguments
all.groups all.groups
...

d debug debug

Author(s)
Toby Dylan Hocking
filltemplate

Description
Fill in occurrences of OBJ$item in the file template with the value in R of L$item.

Usage
filltemplate(L, template)

Arguments

Author(s)
Toby Dylan Hocking

first.bumpup

Description
Label first points, bumping labels up if they collide.

Usage
"first.bumpup"

first.points

Description
Positioning Method for the first of a group of points.

Usage
first.points(d, ...)
first.polygons

Arguments

- d
d...

Author(s)

Toby Dylan Hocking

---

first.polygons  first polygons

Description

Draw a speech polygon to the first point.

Usage

"first.polygons"

---

first.qp  first qp

Description

Label first points from QP solver that ensures labels do not collide.

Usage

"first.qp"
Description
apply a Positioning Method to every group. works like ddply from plyr package, but the grouping column is always called `groups`, and the Positioning Method is not necessarily a function (but can be).

Usage
```r
gapply(d, method, ..., 
groups = "groups")
```

Arguments
- `d` data frame with column `groups`.
- `method` Positioning Method to apply to every group separately.
- `...` additional arguments, passed to Positioning Methods.
- `groups` can also be useful for piece column.

Value
data frame of results after applying FUN to each group in `d`.

Author(s)
Toby Dylan Hocking

description

Description
Makes a function you can use to specify the location of each group independently.

Usage
```r
gapply.fun(expr)
```

Arguments
- `expr` Expression that takes a subset of the `d` data frame, with data from only a single group, and returns the direct label position.
Value

A Positioning Function.

Author(s)

Toby Dylan Hocking

Examples

```r
complicated <- list(dl.trans(x=x+10),
  gapply.fun(d[-2,]),
  rot=c(30,180))
if(require(lattice)){
  direct.label(dotplot(VADeaths,type="o"),complicated,TRUE)
}
```

---

GeomDl

---

Description

ggproto object implementing direct labels.

Usage

```
"GeomDl"
```

---

geom_dl

---

Description

Geom that will plot direct labels.

Usage

```r
geom_dl(mapping = NULL,
  data = NULL, ...,
  method = stop("must specify method= argument"),
  debug = FALSE, stat = "identity",
  position = "identity",
  inherit.aes = TRUE)
```
Arguments

mapping  
aes(label=variable_that_will_be_used_as_groups_in_Positioning_Methods).
data  
data.frame to start with for direct label computation.
method  
Positioning Method for direct label placement, passed to apply.method.
debug  
Show directlabels debugging output?
position  
passed to layer.
inherit.aes  
inherit aes from global ggplot definition?

Author(s)

Toby Dylan Hocking

Examples

if(require(ggplot2)){
  vad <- as.data.frame.table(VADeaths)
names(vad) <- c(“age”, “demographic”, “deaths”)
  ## color + legend
  leg <- ggplot(vad,aes(deaths,age,colour=demographic)) +
    geom_line(aes(group=demographic)) +
    xlim(8,80)
  print(direct.label(leg,list(“last.points”,rot=30)))
  ## this is what direct.label is doing internally:
  labeled <- leg +
    geom_dl(aes(label=demographic), method=list(“last.points”,rot=30)) +
    scale_colour_discrete(guide=“none”)
  print(labeled)
  ## no color, just direct labels!
  p <- ggplot(vad,aes(deaths,age)) +
    geom_line(aes(group=demographic)) +
    geom_dl(aes(label=demographic),method=“top.qp”)
  print(p)
  ## add color:
  p.color <- p+aes(colour=demographic)+
    scale_colour_discrete(guide=“none”)
  print(p.color)
  ## add linetype:
  p.linetype <- p+aes(linetype=demographic)+
    scale_linetype(guide=“none”)
  print(p.linetype)
  ## no color, just direct labels
  if(require(nlme)){
    bwbase <- ggplot(BodyWeight,aes(Time,weight,label=Rat))+
      geom_line(aes(group=Rat))+
      facet_grid(.~Diet)
    bw <- bwbase+geom_dl(method=“last.qp”)
    print(bw)
## add some more direct labels
bw2 <- bw+geom_dl(method="first.qp")
print(bw2)
## add color
colored <- bw2+aes(colour=Rat)+
  scale_colour_discrete(guide="none")
print(colored)
## or just use direct.label if you use color:
print(direct.label(bwbase+aes(colour=Rat),dl.combine("first.qp","last.qp")))
}
## iris data example
giris <- ggplot(iris,aes(Petal.Length,Sepal.Length))+
geom_point(aes(shape=Species))
giris.labeled <- giris+
geom_dl(aes(label=Species),method="smart.grid")+
scale_shape_manual(values=c(setosa=1,virginica=6,versicolor=3),
  guide="none")
##png("~/R/directlabels/www/scatter-bw-ggplot2.png",h=503,w=503)
print(giris.labeled)
##dev.off()
}

get.means
gets means

Description
Positioning Function for the mean of each cluster of points.

Usage
get.means(d, ...)

Arguments
d ... d

Author(s)
Toby Dylan Hocking
getLegendVariables

Description
get the aes which are variable in one legend.

Usage
getLegendVariables(mb)

Arguments
mb

Author(s)
Toby Dylan Hocking

ignore.na

Description
Remove rows for which either x or y is NA

Usage
ignore.na(d, ...)

Arguments
d
...

Author(s)
Toby Dylan Hocking
**in1box**

---

### Description

Calculate how many points fall in a box.

### Usage

```r
in1box(p, box)
```

### Arguments

- `p`  
- `box`  

### Author(s)

Toby Dylan Hocking

---

**in1which**

---

### Description

Calculate which points fall in a box.

### Usage

```r
in1which(p, box)
```

### Arguments

- `p`  
  - data frame of points with columns x and y and many rows.  
- `box`  
  - data frame of 1 row with columns left right top bottom.  

### Author(s)

Toby Dylan Hocking
Description

Calculate for each box how many points are inside.

Usage

```r
inside(boxes, points)
```

Arguments

- `boxes` Data frame of box descriptions, each row is 1 box, need columns `left` `right` `top` `bottom`.
- `points` Data frame of points, each row is 1 point, need columns `x` `y`.

Value

Vector of point counts for each box.

Author(s)

Toby Dylan Hocking

iris.l1.cluster

*Clustering of the iris data with the l1 clusterpath*

Description

The l1 clustering algorithm from the clusterpath package was applied to the iris dataset and the breakpoints in the solution path are stored in this data frame.

Usage

```r
data(iris.l1.cluster)
```

Format

A data frame with 9643 observations on the following 8 variables.

- `row` a numeric vector: row of the original iris data matrix
- `Species` a factor with levels `setosa` `versicolor` `virginica`: Species from corresponding row
- `alpha` a numeric vector: the value of the optimal solution.
- `lambda` a numeric vector: the regularization parameter (ie point in the path).
col a factor with levels Sepal.Length Sepal.Width Petal.Length Petal.Width: column from the original iris data.
gamma a factor with levels 0: parameter from clustering.
norm a factor with levels 1 parameter from clustering.
solver a factor with levels path algorithm used for clustering.

Source
clusterpath package

References
clusterpath article

Examples

data(iris.l1.cluster,package="directlabels")
iris.l1.cluster$y <- iris.l1.cluster$alpha
if(require(ggplot2)){
  p <- ggplot(iris.l1.cluster,aes(lambda,y,group=row,colour=Species))+
    geom_line(alpha=1/4)+
    facet_grid(col~.)
  p2 <- p+xlim(-0.0025,max(iris.l1.cluster$lambda))
  print(direct.label(p2,list(first.points,get.means)))
}

---

label.endpoints label endpoints

Description
Make a Positioning Method that labels a certain x value.

Usage
label.endpoints(FUN, HJUST)

Arguments

FUN FUN(d$x) should return an index of which point to label. for example you can use which.min or which.max.

HJUST hjust of the labels.

Value
A Positioning Method like first.points or last.points.
Author(s)
Toby Dylan Hocking

Description
Make a Positioning Method that will, for every piece, select points and assign a vjust value.

Usage
label.pieces(FUN, VJUST)

Arguments
FUN
VJUST

Author(s)
Toby Dylan Hocking

Description
Label points at the zero before the first nonzero y value.

Usage
“lasso.labels”

Author(s)
Toby Dylan Hocking

Description
Label last points, bumping labels up if they collide.

Usage
“last.bumpup”
last.points  

Description
Positioning Method for the last of a group of points.

Usage
last.points(d, ...)

Arguments
  d  d
  ...  ...

Author(s)
Toby Dylan Hocking

last.polygons  

Description
Draw a speech polygon to the last point.

Usage
"last.polygons"

last.qp  

Description
Label last points from QP solver that ensures labels do not collide.

Usage
"last.qp"
Description

Some lattice plot functions do some magic in the background to translate the data you give them into the data points that are plotted onscreen. We have to replicate this magic in native coordinate space before applying the Positioning Method in cm space. These functions accomplish this translation.

Usage

"lattice.translators"

left.points

Description

Positioning Method for the first of a group of points.

Usage

left.points(d, ...)

Arguments

d
d
...
...

Author(s)

Toby Dylan Hocking

left.polygons

Description

Draw a speech polygon to the first point.

Usage

"left.polygons"
**legends2hide**

**Description**

Extract guides to hide from a ggplot.

**Usage**

`legends2hide(p)`

**Arguments**

- `p`: p

**Value**

NULL if no legends with colour or fill to hide.

**Author(s)**

Toby Dylan Hocking

---

**lines2**

**Description**

Positioning Method for 2 groups of longitudinal data. One curve is on top of the other one (on average), so we label the top one at its maximal point, and the bottom one at its minimal point. Vertical justification is chosen to minimize collisions with the other line. This may not work so well for data with high variability, but then again lineplots may not be the best for these data either.

**Usage**

`lines2(d, offset = 0.3, ...)`

**Arguments**

- `d`: The data.
- `offset`: Offset from 0 or 1 for the vjust values.
- `...`: ignored.

**Author(s)**

Toby Dylan Hocking
**LOPART.ROC**

**ROC curve for LOPART algorithm and competitors**

**Description**

For the LOPART paper we computed ROC curves for predictions of changepoint detection algorithms.

**Usage**

data("LOPART.ROC")

**Format**

A named list of two data frames: points has one row per model/algorithm, roc has one row per point on the ROC curve.

**Source**

Figure/paper describing LOPART algorithm and R package, https://github.com/tdhock/LOPART-paper/blob/master/figure-cv-BIC.R

---

**LOPART100**

**Labeled Optimal Partitioning (LOPART) results**

**Description**

Results of running LOPART algorithm (for changepoint detection in partially labeled data sequence) on a simulated data set of size 100.

**Usage**

data("LOPART100")

**Format**

Named list of data frames: signal has one row per data point, labels has one row per label, segments has one row per segment, cost has one row per feasible last changepoint for model up to t=100 data.

**Source**

Figure/paper describing LOPART algorithm and R package, https://github.com/tdhock/LOPART-paper/blob/master/figure-candidates.R
**make.tiebreaker**

Description

Make a tiebreaker function that can be used with `qp.labels`.

Usage

```r
make.tiebreaker(x.var, tiebreak.var)
```

Arguments

- `x.var`  
- `tiebreak.var`

Author(s)

Toby Dylan Hocking

**maxvar.points**

Description

Do first or last, whichever has points most spread out.

Usage

```r
maxvar.points(d, ...)
```

Arguments

- `d`
- `...`

Author(s)

Toby Dylan Hocking
maxvar.qp

**Description**

Label first or last points, whichever are more spread out, and use a QP solver to make sure the labels do not collide.

**Usage**

```
"maxvar.qp"
```

merge_recurse

**Description**

Copied from reshape.

**Usage**

```
merge_recurse(dfs, ...)
```

**Arguments**

- `dfs`
- `...`

**Author(s)**

Toby Dylan Hocking
Description

Point halfway between the min and max

Usage

midrange(x)

Arguments

x

Author(s)

Toby Dylan Hocking

---

normal.l2.cluster  Clustering of some normal data in 2d with the l2 clusterpath

Description

The l2 clustering algorithm from the clusterpath package was applied to some randomly generated data in 2 dimensions, and the solutions found using the descent algorithm are stored in this data frame.

Usage

data(normal.l2.cluster)

Format

The format is: List of 2 $ pts : 'data.frame': 320 obs. of 3 variables: ..$ class: Factor w/ 8 levels "1","2","3","4",...
1 1 1 1 1 1 1 1 1 ... ..$ x : num [1:320] -2.73 -3.63 -2.13 -1.27 -2.98 ... ..$ y
0 0 0 0 0 0 0 0 0 0 ... .$ row : Factor w/ 320 levels "1","2","3","4",...

  coord_equal()
  print(direct.label(p))
}

---

odd_timings

Odd timings

Description

These timings data made strange output labels with the "right.polygons" method.

Usage

data("odd_timings")

Format

A data frame with 116 observations on the following 4 variables. Plot median.seconds versus N.col using a different line for each fun and a different panel for each captures.

N.col  a numeric vector
fun  a character vector
captures  a numeric vector
median.seconds  a numeric vector

Source

https://github.com/tdhock/nc-article
only.unique.vals

Description
Create a 1-row data.frame consisting of only the columns for which there is only 1 unique value.

Usage
only.unique.vals(d, ...)

Arguments
d
d
...
...

Author(s)
Toby Dylan Hocking

outside.ahull

Description
Calculate closest point on the alpha hull with size of the boxes, and put it outside that point.

Usage
outside.ahull(d, ...)

Arguments
d
d
...
...

Author(s)
Toby Dylan Hocking
outside.chull outside chull

Description
Calculate closest point on the convex hull and put it outside that point. Assume d is the center for each point cloud and then use orig.data to calculate hull.

Usage
outside.chull(d, ...)

Arguments
d
...

Author(s)
Toby Dylan Hocking

panel.superpose.dl panel superpose dl

Description
Call panel.superpose for the data points and then for the direct labels. This is a proper lattice panel function that behaves much like panel.superpose.

Usage
panel.superpose.dl(x,
    y = NULL, subscripts,
    groups, panel.groups,
    method = NULL, .panel.superpose = lattice::panel.superpose,
    type = "p", debug = FALSE,
    ...
)

Arguments
x Vector of x values.
y Vector of y values.
subscripts Subscripts of x,y.groups.
groups Vector of group ids.
panel.superpose.dl

panel.groups  To be parsed for default labeling method, and passed to panel.superpose.
method  Positioning Method for direct labeling. NULL indicates to choose a Positioning Method based on the panel.groups function.
!.panel.superpose  The panel function to use for drawing data points.
type  Plot type, used for default method dispatch.
debug  passed to dlgrob.
...  passed to real panel function, and to translator.

Author(s)
Toby Dylan Hocking

Examples

loci <- data.frame(
  ppp=c(rbeta(800,10,10),rbeta(100,0.15,1),rbeta(100,1,0.15)),
  type=factor(c(rep("NEU",800),rep("POS",100),rep("BAL",100))))
## 3 equivalent ways to make the same plot:
if(require(lattice)){
  print(direct.label( ## most user-friendly
    densityplot(~ppp,loci,groups=type,n=500)
  ))
  print(direct.label( ## exactly the same as above but with specific panel fns
    densityplot(
      ~ppp,loci,groups=type,n=500,
      panel=lattice::panel.superpose,
      panel.groups="panel.densityplot"
    ))
  ## using panel.superpose.dl as the panel function automatically adds
  ## direct labels
  print(densityplot(
    ~ppp,loci,groups=type,n=500,
    panel=panel.superpose.dl,panel.groups="panel.densityplot"
  ))
}
## Exploring custom panel and panel.groups functions
if(require(nlme)){
  ## Say we want to use a simple linear model to explain rat body weight:
  fit <- lm(weight~Time+Diet+Rat,BodyWeight)
  bw <- BodyWeight
  bw$.fitted <- predict(fit,BodyWeight)
  ## lots of examples to come, all with these arguments:
  ratxy <- function(...){
    xyplot(weight~Time|Diet,bw,groups=Rat,type="l",layout=c(3,1),...)
  }
  ## No custom panel functions:
  regular <- ratxy(par.settings=simpleTheme(col=c("red","black")))
  regular <- ratxy()
  print(regular) ## normal lattice plot
  print(direct.label(regular)) ## with direct labels
  ## The direct label panel function panel.superpose.dl can be used to
## display direct labels as well:
print(ratxy(panel=panel.superpose.dl,panel.groups="panel.xyplot"))
print(ratxy(panel=function(...)  
  panel.superpose.dl(panel.groups="panel.xyplot",...)))
## Not very user-friendly, since default label placement is  
## impossible, but these should work:
print(ratxy(  
  panel=panel.superpose.dl,panel.groups=panel.xyplot,  
  method=first.points))
print(ratxy(panel=function(...)  
  panel.superpose.dl(panel.groups=panel.xyplot,...),  
  method=first.points))
## Custom panel.groups functions:
## This panel.groups function will display the model fits:
panel.model <- function(x,subscripts,col.line,...){  
  panel.xyplot(x=x,subscripts=subscripts,col.line=col.line,...)  
  llines(x,bw[subscripts,".fitted"],col=col.line,lty=2)  
}
p <- ratxy(panel=lattice::panel.superpose,panel.groups=panel.model)  
print(p)
## If you use panel.superpose.dl with a custom panel.groups function,  
## you need to manually specify the Positioning Method, since the  
## name of panel.groups is used to infer a default:
print(direct.label(p,method="first.qp"))
print(ratxy(  
  panel=panel.superpose.dl,panel.groups="panel.model",  
  method="first.qp"))
## Custom panel function that draws a box around values:
panel.line1 <- function(ps=lattice::panel.superpose){  
  function(y,...){  
    panel.abline(h=range(y))  
    ps(y=y,...)
  }
}
custom <- ratxy(panel=panel.line1())
print(custom)
print(direct.label(custom))
## Alternate method, producing the same results, but using  
## panel.superpose.dl in the panel function. This is useful for direct  
## label plots where you use several datasets.
print(ratxy(panel=panel.line1(panel.superpose.dl),panel.groups="panel.xyplot"))
## Lattice plot with custom panel and panel.groups functions:  
both <- ratxy(panel=panel.line1(),panel.groups="panel.model")
print(both)
print(direct.label(both,method="first.qp"))
print(ratxy(panel=panel.line1(panel.superpose.dl),  
  panel.groups=panel.model,method="first.qp"))
pkgFun

Description
https://github.com/tdhock/directlabels/issues/2 CRAN won’t complain about this version of :::

Usage
pkgFun(fun, pkg = "ggplot2")

Arguments
fun fun
pkg pkg

Author(s)
Toby Dylan Hocking

polygon.method

Description
Make a Positioning Method that places non-overlapping speech polygons at the first or last points.

Usage
polygon.method(top.bottom.left.right, offset.cm = 0.1, padding.cm = 0.05, custom.colors = NULL)

Arguments
top.bottom.left.right Character string indicating what side of the plot to label.
offset.cm Offset from the polygon to the most extreme data point.
padding.cm Padding inside the polygon.
custom.colors Positioning method applied just before draw.polygons, can set box.color and text.color for custom colors.

Toby Dylan Hocking
positioning.functions  Built-in Positioning Methods for direct label placement

Description

When adding direct labels to a grouped plot, label placement can be specified using a Positioning Method (or a list of them), of the form function(d,...), where d is a data frame of the points to plot, with columns x y groups. The job of the Positioning Method(s) is to return the position of each direct label you want to plot as a data frame, with 1 row for each label. Thus normally a Positioning Method will return 1 row for each group. Several built-in Positioning Methods are discussed below, but you can also create your own, either from scratch or by using dl.indep and dl.trans.

project.onto.segments

Description

Given a point and a set of line segments representing a convex or alpha hull, calculate the closest point on the segments.
**Usage**

```r
project.onto.segments(m, h, debug = FALSE, ...)
```

**Arguments**

- `m`  
  m is 1 row, a center of a point cloud, we need to find the distance to the closest point on each segment of the convex hull.

- `h`  
  Data frame describing the line segments of the convex or alpha hull.

- `debug`  
  debug

- `...`  
  ignored

**Author(s)**

Toby Dylan Hocking

---

**projectionSeconds**  
Timings of projection algorithms

**Description**

Timings of seconds for 3 projection algorithms.

**Usage**

```r
data(projectionSeconds)
```

**Format**

A data frame with 603 observations on the following 6 variables.

- `vector.length`  
  a numeric vector

- `method`  
  a factor with levels Heap Random Sort

- `mean`  
  a numeric vector

- `sd`  
  a numeric vector

- `min`  
  a numeric vector

- `max`  
  a numeric vector

qp.labels

Make a Positioning Method for non-overlapping lineplot labels

Description

Use a QP solver to find the best places to put the points on a line, subject to the constraint that they should not overlap.

Usage

qp.labels(target.var,
   lower.var, upper.var,
   order.labels = function(d) order(d[, target.var]),
   limits = NULL)

Arguments

target.var           Variable name of the label target.
lower.var            Variable name of the lower limit of each label bounding box.
upper.var            Variable name of the upper limit of each label bounding box.
order.labels         Function that takes the data.frame of labels and returns an ordering, like from the order function. That ordering will be used to reorder the rows. This is useful to e.g. break ties when two groups have exactly the same value at the endpoint near the label.
limits               Function that takes the data.frame of labels an returns a numeric vector of length 2. If finite, these values will be used to add constraints to the QP: limits[1] is the lower limit for the first label’s lower.var, and limits[2] is the upper limit for the last labels’s upper.var. Or NULL for no limits.

Value

Positioning Method that adjusts target.var so there is no overlap of the label bounding boxes, as specified by upper.var and lower.var.

Author(s)

Toby Dylan Hocking

Examples

SegCost$error <- factor(SegCost$error,c("FP","FN","E","I"))
if(require(ggplot2)){
   fp.fn.colors <- c(FP="skyblue",FN="#E41A1C",I="black",E="black")
   fp.fn.sizes <- c(FP=2.5,FN=2.5,I=1,E=1)
   fp.fn.linetypes <- c(FP="solid",FN="solid",I="dashed",E="solid")
   err.df <- subset(SegCost,type!="Signal")
kplot <- ggplot(err.df,aes(segments,cost)) +
   geom_line(aes(colour=error,size=error,linetype=error)) +
   facet_grid(type~bases.per.probe) +
   scale_linetype_manual(values=fp.fn.linetypes) +
   scale_colour_manual(values=fp.fn.colors) +
   scale_size_manual(values=fp.fn.sizes) +
   scale_x_continuous(limits=c(0,20),breaks=c(1,7,20),minor_breaks=NULL) +
   theme_bw() + theme(panel.margin=grid::unit(0,"lines"))

## The usual ggplot without direct labels.
print(kplot)

## Get rid of legend for direct labels.
no.leg <- kplot+guides(colour="none",linetype="none",size="none")

## Default direct labels.
direct.label(no.leg)

## Explore several options for tiebreaking and limits. First let's
## make a qp.labels Positioning Method that does not tiebreak.
no.tiebreak <- list("first.points",
                    "calc.boxes",
                    qp.labels("y","bottom","top"))
direct.label(no.leg, no.tiebreak)

## Look at the weird labels in the upper left panel. The E curve is
## above the FN curve, but the labels are the opposite! This is
## because they have the same y value on the first points, which are
## the targets for qp.labels. We need to tiebreak.
qp.break <- qp.labels("y","bottom","top",make.tiebreaker("x","y"))
tiebreak <- list("first.points",
                 "calc.boxes",
                 "qp.break")
direct.label(no.leg, tiebreak)

## Enlarge the text size and spacing.
tiebreak.big <- list("first.points",
                    cex=2,
                    "calc.boxes",
                    dl.trans(h=1.25*h),
                    "calc.borders",
                    "qp.break")
direct.label(no.leg, tiebreak.big)

## Even on my big monitor, the FP runs off the bottom of the screen
## in the top panels. To avoid that you can specify a limits
## function.

## Below, the ylims function uses the limits of each panel, so
## labels appear inside the plot region. Also, if you resize your
## window so that it is small, you can see that the text size of the
## labels is decreased until they all fit in the plotting region.
reduce.cex

```r
qp.limited <- qp.labels("y","bottom","top",make.tiebreaker("x","y"),ylimits)
tiebreak.lim <- list("first.points",
cex=2,
  "calc.boxes",
dl.trans(h=1.25*h),
  "calc.borders",
  "qp.limited")
direct.label(no.leg, tiebreak.lim)
}
```

---

reduce.cex  
reduce cex

**Description**

If edges of the text are going out of the plotting region, then decrease cex until it fits. We call `calc.boxes inside`, so you should set cex before using this.

**Usage**

```
reduce.cex(sides)
```

**Arguments**

- **sides**  
  string: lr (left and right) or tb (top and bottom).

**Author(s)**

Toby Dylan Hocking

**Examples**

```r
if(require(lars) && require(ggplot2)){
  data(diabetes,package="lars",envir=environment())
  X <- diabetes$x
  colnames(X) <- paste(colnames(X), colnames(X))
  fit <- lars(X,diabetes$y,type="lasso")
  beta <- scale(coef(fit),FALSE,1/fit$normx)
  arclength <- rowSums(abs(beta))
  path.list <- list()
  for(variable in colnames(beta)){
    standardized.coef <- beta[, variable]
    path.list[[variable]] <-
      data.frame(step=seq_along(standardized.coef),
       arclength,
       variable,
       standardized.coef)
  }
  path <- do.call(rbind, path.list)
}
```
p <- ggplot(path,aes(arclength,standardized.coef,colour=variable)) +
        geom_line(aes(group=variable))
## the legend isn't very helpful.
print(p)
## add direct labels at the end of the lines.
direct.label(p, "last.points")
## on my screen, some of the labels go off the end, so we can use
## this Positioning Method to reduce the text size until the labels
## are on the plot.
direct.label(p, list("last.points",reduce.cex("lr")))
## the default direct labels for lineplots are similar.
direct.label(p)

reduce.cex.lr
reduce cex lr

Description

If edges of the text are going left or right out of the plotting region, then decrease cex until it fits.

Usage

reduce.cex.lr(d, ...)

Arguments

d d
...

Author(s)

Toby Dylan Hocking

reduce.cex.tb
reduce cex tb

Description

If edges of the text are going over the top or bottom of the plotting region, then decrease cex until it fits.

Usage

reduce.cex.tb(d, ...)
Arguments
d ... d

Author(s)
Toby Dylan Hocking

---

derhmtlescape
derhmtlescape

Description
for standards compliance we should escape <&

Usage
derhmtlescape(code)

Arguments
code R code to be displayed on a HTML page between pre tags.

Value
Standards compliant HTML to display.

Author(s)
Toby Dylan Hocking

---

deright.points
deright points

Description
Positioning Method for the last of a group of points.

Usage
deright.points(d, ...)

Arguments
d ... d
... ...
**Author(s)**
Toby Dylan Hocking

---

**Description**
Draw a speech polygon to the last point.

**Usage**
"right.polygons"

---

**SegCost**
*Cost of segmentation models*

**Description**
20 segmentation models were fit to 2 simulated signals, and several different error measures were used to quantify the model fit.

**Usage**
data(SegCost)

**Format**
A data frame with 560 observations on the following 5 variables.
- **bases.per.probe** a factor with levels 374 7: the sampling density of the signal.
- **segments** numeric: the model complexity measured using number of segments.
- **cost** numeric: the cost value.
- **error** a factor with levels E FP FN I: what kind of error? FP = False Positive, FN = False Negative, I = Imprecision, E = Error (sum of the other terms).

**Source**
smart.grid

Description

Search the plot region for a label position near the center of each point cloud.

Usage

"smart.grid"

static.labels

Description

to hard-code label positions...

Usage

static.labels(x, y, groups, ...)

Arguments

x
y
groups
...

Author(s)

Toby Dylan Hocking
Description
Support Vector Machine density estimation (1-SVM) was applied to a set of negative control samples, and then used to test on a positive control.

Usage
data(svmtrain)

Format
A data frame with 378 observations on the following 5 variables.

replicate a factor with levels 1 2 3, the experimental replicate. We fit 1-SVM models to each replicate separately.
rate a numeric vector, the percent of observations that were outside the trained model.
data a factor with levels KIF11 test train, which set of observations did we measure. test and train are each 50% random splits of the negative controls in the experiment, and KIF11 is the positive control in the experiment.
gamma a numeric vector, the tuning parameter of the radial basis function kernel.
u a numeric vector, the regularization parameter of the 1-SVM.

description top bumptwice

description Label the tops, bump labels up to avoid other labels, then to the side to avoid collisions with points.

Usage
top.bumptwice(d, debug = FALSE, ...)

Arguments
d d
d debug debug ...
...

Author(s)
Toby Dylan Hocking
### top.bumpup

**Description**

Label the tops, but bump labels up to avoid collisions.

**Usage**

```
"top.bumpup"
```

### top.pieces

**Description**

Positioning Method for the top of a group of points.

**Usage**

```
top.pieces(d, ...)
```

**Arguments**

```
  d       d
  ...     ... 
```

**Author(s)**

Toby Dylan Hocking

### top.points

**Description**

Positioning Method for the top of a group of points.

**Usage**

```
top.points(d, ...)
```
Argument(s)

d
d...

Author(s)

Toby Dylan Hocking

description

Draw a speech polygon to the top point.

Usage

"top.polygons"

description

Label points at the top, making sure they don’t collide.

Usage

"top.qp"
Description

Show the ggplot2 legend, for comparison.

Usage

uselegend.ggplot(p, ...)

Arguments

p The ggplot object.
...

Author(s)

Toby Dylan Hocking

Description

Add a legend to a trellis plot, for comparison.

Usage

uselegend.trellis(p,
...

Arguments

p The trellis object.
...

Author(s)

Toby Dylan Hocking
Description
Make a Positioning Function from a set of points on a vertical line that will be spaced out using \texttt{qp.labels}.

Usage
\texttt{vertical.qp(M)}

Arguments
\texttt{M}

Author(s)
Toby Dylan Hocking

--------------------------------------------------------

Description
Point in the middle of the min and max for each group.

Usage
\texttt{visualcenter(d, ...)}

Arguments
\texttt{d}
\texttt{...}

Author(s)
Toby Dylan Hocking
Description
Return the positions of the plot horizontal limits in cm, for use as the limit argument to `qp.labels`.

Usage
`xlimits(...)`

Arguments

Author(s)
Toby Dylan Hocking

Description
Return the positions of the plot vertical limits in cm, for use as the limit argument to `qp.labels`.

Usage
`ylimits(...)`

Arguments
